Abstract. We study the long-time behavior for continuous-time Markov processes on the state space \( \mathbb{R}_{\geq 0} := [0, \infty) \), which arise as unique strong solutions to stochastic equations with jumps. We establish, under a global dissipativity condition combined with a comparison principle, exponential ergodicity in various Wasserstein distances on \( \mathbb{R}_{\geq 0} \). Our main emphasis lies on the derivation of these estimates under minimal moment conditions to be imposed on the associated Lévy measures of the noises. We apply our method to continuous-state branching processes with immigration (shorted as CBI processes), to nonlinear CBI processes, and finally to CBI processes in Lévy random environments.

1. Introduction

The study of long-time behavior for continuous-time Markov processes is a classical and still popular topic in probability theory. In this paper we investigate this problem for jump-diffusions on the state space \( \mathbb{R}_{\geq 0} := [0, \infty) \), which include interesting classes of processes such as continuous-state branching processes with immigration (see, e.g., Li (2011); Pardoux (2016)), possibly in Lévy random environments (see He et al. (2018); Palau and Pardo (2017)), continuous-state nonlinear branching processes (see Li et al. (2019)), and TCP processes (see, e.g., Bardet et al. (2013); Chafaï et al.).
More precisely, we investigate the long-time behaviour for the Markov process determined by the stochastic equation

\[
X_t = X_0 + \int_0^t b(X_s) \, ds + \int_0^t \int_E \sigma(X_s, u) \, W(\, ds, du) + \int_0^t \int_{U_0} g_0(X_{s-}, u) \, \widetilde{N}_0(\, ds, du) + \int_0^t \int_{U_1} g_1(X_{s-}, u) \, N_1(\, ds, du), \quad t \geq 0, \tag{1.1}
\]

where \(W(\, ds, du)\) is a Gaussian white noise on \(\mathbb{R}_{\geq 0} \times E\), \(N_0(\, ds, du)\) is a Poisson random measure on \(\mathbb{R}_{\geq 0} \times U_0\), \(N_1(\, ds, du)\) is a Poisson random measure on \(\mathbb{R}_{\geq 0} \times U_1\), and \(\widetilde{N}_0\) denotes the compensated Poisson random measure associated with \(N_0\). The precise conditions we impose on the coefficients \(b, \sigma, g_0, g_1\) and on the noise terms are given in Section 3. A strong solution to (1.1) is, by definition, a nonnegative càdlàg process \(\{X_t : t \geq 0\}\) that is adapted to the augmented natural filtration generated by \(W(\, ds, du)\), \(N_0(\, ds, du)\) and \(N_1(\, ds, du)\) and that satisfies the equation (1.1) almost surely for every \(t \geq 0\). The existence and uniqueness of strong solutions were studied, e.g., in Fu and Li (2010), Dawson and Li (2012), and Li and Pu (2012). Additional related results for stochastic equations on \(\mathbb{R}_{\geq 0}\) can be found in Li and Mytnik (2011) as well as in Fourrier (2013).

Let \(\{P_t(x, dy) : t, x \geq 0\}\) be the transition probabilities of the Markov process with state space \(\mathbb{R}_{\geq 0}\) obtained from (1.1) and let \(\mathcal{P}(\mathbb{R}_{\geq 0})\) be the space of all Borel probability measures over \(\mathbb{R}_{\geq 0}\). We call \(\pi \in \mathcal{P}(\mathbb{R}_{\geq 0})\) an invariant measure for \(\{P_t(x, dy) : t, x \geq 0\}\), if

\[
\int_{\mathbb{R}_{\geq 0}} P_t(x, dy) \pi(dx) = \pi(dy), \quad t \geq 0.
\]

Existence of invariant measures can be shown by a compactness argument, see, e.g., Section 9 in Chapter 4 of Ethier and Kurtz (1986) for some sufficient condition and often relies on a Lyapunov drift condition. Unlike existence, uniqueness of the invariant measure is a more demanding mathematical problem and can be deduced, e.g., from the convergence of \(P_t(x, dy)\) to \(\pi\). In order to study such convergence, let us define, for \(\varrho, \tilde{\varrho} \in \mathcal{P}(\mathbb{R}_{\geq 0})\), the Wasserstein distance

\[
W_d(\varrho, \tilde{\varrho}) = \inf \left\{ \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} d(x, y) H(dx, dy) : H \text{ is a coupling of } (\varrho, \tilde{\varrho}) \right\}, \tag{1.2}
\]

where \(d\) is a suitably chosen metric on \(\mathbb{R}_{\geq 0}\). Natural examples for \(d\), among others, are \(d(x, y) = \|x - y\|\) corresponding to the total variation distance and \(d(x, y) = |x - y|\) in accordance with the Kantorovich-Rubinstein distance. In Section 2 we collect some basic properties of \(W_d\) while a detailed treatment of Wasserstein distances is provided in the monograph of Villani (2009).

We call a Markov process exponentially ergodic in \(W_d\), if there exists a constant \(A > 0\) and a function \(K : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}\) satisfying

\[
W_d(P_t(x, \cdot), \pi) \leq K(x)e^{-At}, \quad t, x \geq 0.
\]

A widely used approach for the study of exponential ergodicity in the total variation distance (i.e. \(d(x, y) = 1_{\{x \neq y\}}\)) is due to Meyn and Tweedie (1993, 2009). The essential obstacle when applying their approach lies within the “irreducibility of a skeleton chain”. To prove this, it is sufficient and customary to verify that \(P_t(x, dy)\) has a jointly continuous density which is strictly positive. While such an approach is suitable for diffusion processes, the situation is more delicate and requires a custom-tailored analysis when dealing with Markov processes with jumps. Albeit being challenging, the approach of Meyn and Tweedie has already been successfully applied to diverse Markov processes with jumps. Another approach to prove ergodicity of Markov processes is based on the construction of successful couplings. Such construction is usually closely related with the mathematical model at hand and often a difficult task, see, e.g., Butkovsky (2014); Eberle (2016); Peng and Zhang (2018); Wang (2016).
In this work we provide a simple approach to exponential ergodicity in the Wasserstein distance $W_d$ with $d(x, y) = |x - y|^\lambda$, $\lambda \in (0, 1]$ or $d(x, y) = \log(1 + |x - y|)$ for Markov processes on $\mathbb{R}_{\geq 0}$ which can be constructed as strong solutions of stochastic equations satisfying the comparison principle. Indeed, using the comparison principle we construct a monotone coupling for $(X_t^x, X_t^y)$ with $X_t^x = x$ and $X_t^y = y$ obtained from (1.1). This coupling allows us to estimate the Wasserstein distance and subsequently prove the existence, uniqueness of invariant measures, and exponential ergodicity in the Wasserstein distance. The corresponding results are formulated in Section 3 and extend the method developed in Friesen et al. (2020b), where affine processes on the canonical state space have been studied, to a general class of Markov processes on $\mathbb{R}_{\geq 0}$. For simplicity, we consider only the one-dimensional case. However, using the arguments based on the comparison principle similar to Friesen et al. (2020a), one may extend most of the results of this paper also to multi-dimensional settings, i.e., to Markov processes on state space $\mathbb{R}^m_{\geq 0} = \{x \in \mathbb{R}^m : x_k \geq 0, \forall k = 1, \ldots, m\}$.

To illustrate the usage of our results obtained in Section 3, we apply them in Section 4 to continuous-state branching processes and nonlinear continuous-state branching processes, as well as in Section 5 to continuous-state branching processes in Lévy environments. All these processes have in common that, the coefficients in front of the noise terms (continuous and pure-jump noise) are typically degenerate at the boundary 0 and hence the methods from Douc et al. (2009); Eberle et al. (2019); Kulik (2009); Veretennikov (1987) do not directly apply here.

2. Some basic properties of Wasserstein distances

By $\mathcal{P}(\mathbb{R}_{\geq 0})$ we denote the space of all Borel probability measures over $\mathbb{R}_{\geq 0}$. Given $\varrho, \varrho' \in \mathcal{P}(\mathbb{R}_{\geq 0})$, a coupling $H$ of $(\varrho, \varrho')$ is a Borel probability measure on $\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$ which has marginals $\varrho$ and $\varrho'$, respectively. We write $\mathcal{H}(\varrho, \varrho')$ for the collection of all such couplings. Let $d$ be a metric on $\mathbb{R}_{\geq 0}$ such that $(\mathbb{R}_{\geq 0}, d)$ is a complete separable metric space and define

$$
\mathcal{P}_d(\mathbb{R}_{\geq 0}) = \left\{ \varrho \in \mathcal{P}(\mathbb{R}_{\geq 0}) : \int_{\mathbb{R}_{\geq 0}} \inf_{\varrho' \in \mathcal{P}(\mathbb{R}_{\geq 0})} d(x, 0)\varrho'(dx) < \infty \right\}.
$$

The Wasserstein distance on $\mathcal{P}_d(\mathbb{R}_{\geq 0})$ is defined by (1.2) Note that, since $\varrho$ and $\varrho'$ belong to $\mathcal{P}_d(\mathbb{R}_{\geq 0})$, the expression $W_d(\varrho, \varrho')$ is finite. Moreover, it can be shown that this infimum is attained (see Villani (2009, p.95)), i.e., there exists $H \in \mathcal{H}(\varrho, \varrho')$ such that

$$
W_d(\varrho, \varrho') = \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} d(x, y)H(dx, dy). \tag{2.1}
$$

Since $(\mathbb{R}_{\geq 0}, d)$ is assumed to be a complete separable metric space, according to Villani (2009, Theorem 6.16), $(\mathcal{P}_d(\mathbb{R}_{\geq 0}), W_d)$ is also a complete separable metric space. In the remainder of the article, we will use the following particular examples.

Example 2.1.

(a) If $d_{TV}(x, y) = 1_{\{x \neq y\}}$, then $\mathcal{P}_{d_{TV}}(\mathbb{R}_{\geq 0}) = \mathcal{P}(\mathbb{R}_{\geq 0})$ and

$$
W_{d_{TV}}(\varrho, \varrho') = \frac{1}{2}\|\varrho - \varrho'||_{TV} := \frac{1}{2}\sup \{|\varrho(A) - \varrho'(A)| : A \subset \mathbb{R} \text{ Borel set}\}
$$

is the total variation distance. Note that in this case $(\mathbb{R}_{\geq 0}, d_{TV})$ is not separable. However, $W_{d_{TV}}$ still defines a metric on $\mathcal{P}_{d_{TV}}(\mathbb{R}_{\geq 0})$ with respect to which this space is complete.

(b) For $\lambda \in (0, 1]$, the Wasserstein-$\lambda$-distance corresponds to $d_\lambda(x, y) = |x - y|^\lambda$, where

$$
\mathcal{P}_{d_\lambda}(\mathbb{R}_{\geq 0}) := \left\{ \varrho \in \mathcal{P}(\mathbb{R}_{\geq 0}) : \int_{\mathbb{R}_{\geq 0}} x^\lambda \varrho(dx) < \infty \right\}.
$$

For simplicity, we write $(\mathcal{P}_\lambda(\mathbb{R}_{\geq 0}), W_\lambda)$ instead of $(\mathcal{P}_{d_\lambda}(\mathbb{R}_{\geq 0}), W_{d_\lambda})$. 

Lemma 2.3. below. This proves the first inequality. The second inequality can be shown in the same way, since Lemma 2.2.

\[ \rho \in \mathcal{P}(\mathbb{R}_{\geq 0}) : \int_{\{x > 1\}} \log(x) \rho(dx) < \infty \]

Similarly as in (b), we write \( (\mathcal{P}_{\log}(\mathbb{R}_{\geq 0}), W_{\log}) \) instead of \( (\mathcal{P}_{\log}(\mathbb{R}_{\geq 0}), W_{d_{\log}}) \).

(d) Finally, we will use the following auxiliary metric defined by \( d_{\log}^R(x, y) = 1 \wedge |x - y| \). The corresponding Wasserstein distance is then well-defined on \( \mathcal{P}_{d_{\log}^R}(\mathbb{R}_{\geq 0}) = \mathcal{P}(\mathbb{R}_{\geq 0}) \).

We will need the following simple relation between the distances \( W_\lambda \) and \( W_{\log} \).

**Lemma 2.2.** Let \( \lambda \in (0, 1] \). For all \( \varrho, \tilde{\varrho} \in \mathcal{P}(\mathbb{R}_{\geq 0}) \) it holds that
\[
W_{\log}(\varrho, \tilde{\varrho}) \leq \log (1 + W_1(\varrho, \tilde{\varrho})) \quad \text{and} \quad W_\lambda(\varrho, \tilde{\varrho}) \leq (W_1(\varrho, \tilde{\varrho}))^\lambda.
\]

**Proof:** Let \( H \) be the optimal coupling for \( W_1(\varrho, \tilde{\varrho}) \). Then using that \([0, \infty) \ni x \mapsto \log(1 + x)\) is concave, we get
\[
W_{\log}(\varrho, \tilde{\varrho}) \leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} \log(1 + |x - y|) H(dx, dy)
\]
\[
\leq \log \left( 1 + \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} |x - y| H(dx, dy) \right)
\]
\[
= \log (1 + W_1(\varrho, \tilde{\varrho})).
\]

This proves the first inequality. The second inequality can be shown in the same way, since \([0, \infty) \ni x \mapsto x^\lambda\) is also concave.

One simple but important property of Wasserstein distances is their convexity as formulated below.

**Lemma 2.3.** Let \( d \) be a metric such that \( (\mathbb{R}_{\geq 0}, d) \) is a complete separable metric space. Let \( \varrho, \tilde{\varrho} \in \mathcal{P}_d(\mathbb{R}_{\geq 0}) \) and suppose that \( P_t(x, dy) \) is a Markov kernel on \( \mathbb{R}_{\geq 0} \). Then, for any \( H \in \mathcal{H}(\varrho, \tilde{\varrho}) \), we have
\[
W_d \left( \int_{\mathbb{R}_{\geq 0}} P(x, \cdot) \varrho(dx), \int_{\mathbb{R}_{\geq 0}} P(x, \cdot) \tilde{\varrho}(dx) \right) \leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} W_d(P(x, \cdot), P(y, \cdot)) H(dx, dy).
\]

Note that this assertion also holds for the total variation distance. For a proof we refer the reader to Villani (2009, Theorem 4.8). The convolution between measures \( \varrho \) and \( \tilde{\varrho} \) on \( \mathbb{R}_{\geq 0} \) is denoted by \( \varrho * \tilde{\varrho} \). We close the presentation with a useful convolution estimate for Wasserstein distances.

**Lemma 2.4.** Let \( d \) be a metric such that \( (\mathbb{R}_{\geq 0}, d) \) is a complete separable metric space. Suppose that \( d(x + y, \bar{x} + y) \leq d(x, \bar{x}) \) for \( x, \bar{x}, y \geq 0 \). Let \( \varrho, \tilde{\varrho}, g \in \mathcal{P}_d(\mathbb{R}_{\geq 0}) \). Then
\[
W_d(\varrho * g, \tilde{\varrho} * g) \leq W_d(\varrho, \tilde{\varrho}).
\]

**Proof:** For a function \( h \) on \( \mathbb{R}_{\geq 0} \), we define \( \| h \|_{\text{Lip}} = \sup_{x \neq y} \frac{|h(x) - h(y)|}{d(x, y)} \) and a new function \( h_g \) as \( h_g(x) = \int_{\mathbb{R}_{\geq 0}} h(x + y) g(dy) \), \( x \geq 0 \). Note that if \( \| h \|_{\text{Lip}} \leq 1 \), then
\[
|h_g(x) - h_g(x')| \leq \int_{\mathbb{R}_{\geq 0}} |h(x + y) - h(x' + y)| g(dy)
\]
\[
\leq \| h \|_{\text{Lip}} \int_{\mathbb{R}_{\geq 0}} d(x + y, x' + y) g(dy)
\]
\[
\leq \| h \|_{\text{Lip}} \int_{\mathbb{R}_{\geq 0}} d(x, x') g(dy) \leq d(x, x'),
\]
showing that \( \| h_g \|_{\text{Lip}} \leq 1 \). Combining this observation with the Kantorovich-Duality, we obtain

\[
W_d(\varrho \ast g, \tilde{\varrho} \ast g) = \sup_{\| h \|_{\text{Lip}} \leq 1} \left| \int_{\mathbb{R}^2} h(x)(\varrho \ast g)(dx) - \int_{\mathbb{R}^2} h(x)(\tilde{\varrho} \ast g)(dx) \right|
\]

\[
= \sup_{\| h \|_{\text{Lip}} \leq 1} \left| \int_{\mathbb{R}^2} h_g(x)g(dx) - \int_{\mathbb{R}^2} h_g(x)\tilde{g}(dx) \right|
\]

\[
\leq \sup_{\| h \|_{\text{Lip}} \leq 1} \left| \int_{\mathbb{R}^2} h(x)g(dx) - \int_{\mathbb{R}^2} h(x)\tilde{g}(dx) \right| = W_d(g, \tilde{g}).
\]

\[\square\]

Although we formulated Lemma 2.3 and 2.4 on the state space \( \mathbb{R}_{\geq 0} \), it is clear that they naturally extend to more abstract state spaces.

3. Stochastic equations of nonnegative processes with jumps

Let \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})\) be a filtered probability space with the usual hypotheses, let \( E, U_0 \), and \( U_1 \) be complete separable metric spaces, \( \mathcal{X}(du) \), \( \mu_0(du) \) and \( \mu_1(du) \) be \( \sigma \)-finite measures on \( E, U_0 \) and \( U_1 \), respectively. Then let \( W(dt, du) \) be an \((\mathcal{F}_t)_{t \geq 0}\)-Gaussian white noise on \( \mathbb{R}_{\geq 0} \times E \) with intensity measure \( dt \mathcal{X}(dz) \), and let \( N_0(dt, du) \) and \( N_1(dt, du) \) be \((\mathcal{F}_t)_{t \geq 0}\)-Poisson random measures on \( \mathbb{R}_{\geq 0} \times U_0 \) and \( \mathbb{R}_{\geq 0} \times U_1 \) with intensities \( dt \mu_0(du) \) and \( dt \mu_1(du) \), respectively. Denote by \( \tilde{N}_0(dt, du) := N_0(dt, du) - dt \mu_0(du) \) the compensated Poisson random measure of \( N_0(dt, du) \). Suppose that the random objects \( W(dt, du), N_0(dt, du), \) and \( N_1(dt, du) \) are mutually independent.

We call parameters \((b, \sigma, g_0, g_1)\) admissible, if they satisfy the following set of conditions:

- \( x \mapsto b(x) \) is continuous on \( \mathbb{R}_{\geq 0} \) and satisfies \( b(0) \geq 0 \);
- \( (x, u) \mapsto \sigma(x, u) \) is a Borel function on \( \mathbb{R}_{\geq 0} \times E \) satisfying \( \sigma(0, u) = 0 \) for \( u \in E \);
- \( (x, u) \mapsto g_0(x, u) \) is a Borel function on \( \mathbb{R}_{\geq 0} \times U_0 \) satisfying \( g_0(0, u) = 0 \) and \( g_0(x, u) + x \geq 0 \) for \( x > 0 \) and \( u \in U_0 \);
- \( (x, u) \mapsto g_1(x, u) \) is a Borel function on \( \mathbb{R}_{\geq 0} \times U_1 \) satisfying \( g_1(x, u) + x \geq 0 \) for \( x \in \mathbb{R}_{\geq 0} \) and \( u \in U_1 \).

While the above conditions are natural to ensure solutions of (1.1) to be non-negative, existence and uniqueness of solutions do require a set of additional technical conditions introduced below.

3(a) There is a constant \( K_0 \geq 0 \) and a Borel function \( (x, u) \mapsto \mathcal{F}_1(x, u) \) on \( \mathbb{R}_{\geq 0} \times U_1 \) such that \( \sup_{y \in [0, x]} |g_1(y, u)| \leq \mathcal{F}_1(x, u) \) and for \( x \geq 0 \)

\[
b(x) + \int_{U_1} 1 \wedge |\mathcal{F}_1(x, u)| \mu_1(du) \leq K_0(2 + x);
\]

3(b) There exist continuous functions \( b_1, b_2 \) such that \( b(x) = b_1(x) - b_2(x) \) and \( x \mapsto b_2(x) \) is nondecreasing. Finally, for each \( j \geq 1 \) there is a nondecreasing, continuous, concave function \( z \mapsto r_j(z) \) on \( \mathbb{R}_{\geq 0} \) such that \( \int_{0^+} r_j(z)^{-1} dz = \infty \) and for all \( 0 \leq x, y \leq j \)

\[
|b_1(x) - b_1(y)| + \int_{U_1} |g_1(x, u) - g_1(y, u)| \mu_1(du) \leq r_j(|x - y|);
\]

3(c) For each \( j \geq 1 \) there is a constant \( A_j > 0 \) such that for \( 0 \leq x, y \leq j \)

\[
\int_{E} |\sigma(x, u) - \sigma(y, u)|^2 \mathcal{X}(du) \leq A_j|x - y|,
\]
the function \( x \mapsto \int_E \sigma(x,u)\mathcal{Z}(du) \) is continuous, and there exists a constant \( K_1 > 0 \) such that for \( x \geq 0 \)
\[ 
\int_E \sigma(x,u)^2\mathcal{Z}(du) \leq K_1(2+x)^2, \quad x \geq 0;
\]

(3.d) There is a non-decreasing function \( x \mapsto L(x) \) on \( \mathbb{R}_{\geq 0} \) and a Borel function \( (x,u) \mapsto \mathcal{g}_0(x,u) \) on \( \mathbb{R}_{\geq 0} \times U_0 \) so that \( \sup_{y \in [0,x]} |g_0(y,u)| \leq \mathcal{g}_0(x,u) \) and
\[ 
\int_{U_0} \left( \mathcal{g}_0(x,u) \land \mathcal{g}_0(x,u)^2 \right) \mu_0(du) \leq L(x)
\]
for every \( x \geq 0 \), and there exists a constant \( K_2 \geq 0 \) such that
\[ 
\int_{U_0} 1_{\{|g_0(x,u)| \leq 1\}} |g_0(x,u)|^2 \mu_0(du) \leq K_2(2+x)^2
\]
holds for each \( x \geq 0 \). Moreover, for each \( j \geq 1 \) there exists a constant \( B_j \geq 0 \) such that
\[ 
\int_{U_0} \left( |g_0(x,u) - g_0(y,u)| \land (|g_0(x,u) - g_0(y,u)|^2) \right) \mu_0(du) \leq B_j|x-y|
\]
holds for all \( 0 \leq x, y \leq j \).

(3.e) The functions \( x \mapsto x + g_0(x,u) \) and \( x \mapsto x + g_1(x,u) \) are non-decreasing for each \( u \in U_0 \) or \( u \in U_1 \), respectively.

**Definition 3.1.** Equation (1.1) is said to have the comparison property, if for any non-negative \( \mathcal{F}_0 \)-measurable random variables \( X_0, Y_0 \) and corresponding solutions \( \{X_t : t \geq 0\} \) and \( \{Y_t : t \geq 0\} \) to (1.1), it holds that: if \( \mathbb{P}(X_0 \leq Y_0) = 1 \), then \( \mathbb{P}(X_t \leq Y_t \text{ for all } t \geq 0) = 1 \).

Before we formulate our main statement, we introduce the following conditions on the big jumps of the process.

\( (m)_\lambda \) : There exists \( \lambda > 0 \) and \( K_\lambda > 0 \) such that for all \( x \geq 0 \),
\[ 
\int_{U_1} 1_{\{|g_1(x,u)| > 1\}} |g_1(x,u)|^\lambda \mu_1(du) \leq K_\lambda (2+x)^{\min\{1,\lambda\}}, \quad (3.1)
\]
\[ 
\int_{U_0} 1_{\{|g_0(x,u)| > 1\}} |g_0(x,u)|^{\max\{1,\lambda\}} \mu_0(du) \leq K_\lambda (2+x)^{\rho(\lambda)},
\]
where \( \rho(\lambda) = \lambda \mathbb{I}_{(0,1]}(\lambda) + \mathbb{I}_{(1,2]}(\lambda) + 2\mathbb{I}_{[2,\infty)} \).

\( (m)_{\log} \) : There exists a constant \( K_{\log} > 0 \) such that for all \( x \geq 0 \),
\[ 
\int_{U_1} 1_{\{|g_1(x,u)| > 1\}} \log(1 + |g_1(x,u)|) \mu_1(du) \leq K_{\log} (2+x), \quad (3.2)
\]
\[ 
\int_{U_0} 1_{\{|g_0(x,u)| > 1\}} |g_0(x,u)| \mu_0(du) \leq K_{\log} (2+x).
\]

**Remark 3.2.** If condition \( (m)_\lambda \) holds for \( \lambda \in (0,2] \), then also condition \( (m)_{\log} \) holds true.

The next theorem provides the existence, uniqueness and comparison property for solutions of (1.1).

**Theorem 3.3.** Let \( (b,\sigma,g_0,g_1) \) be admissible parameters, suppose that conditions (3.a) – (3.e) are satisfied. Suppose that one of the following two conditions holds:
(i) condition \( (m)_\lambda \) holds for some \( \lambda > 0 \) and \( \mathbb{E}[X_0^\lambda] < \infty \);
(ii) condition \( (m)_{\log} \) is satisfied and \( \mathbb{E}[\log(2+X_0)] < \infty \).
Then there exists a unique strong solution \( \{X_t : t \geq 0\} \) of (1.1). This solution satisfies, under condition (i) the estimate
\[ 
\mathbb{E}[X_t^\lambda] \leq \mathbb{E}[(2+X_0)^\lambda] \exp(c(\lambda)t), \quad t \geq 0,
\]
Lemma 3.4. Let \( \lambda > 0 \) be some constant, while under condition (ii) it satisfies
\[
\mathbb{E} [\log(2 + X_t)] \leq \mathbb{E} [\log(2 + X_0)] + c_{\log} t, \quad t \geq 0,
\]
where \( c_{\log} > 0 \) is some constant. Moreover, (1.1) has the comparison property.

Proof: The existence and uniqueness of a \([0, \infty]\)-valued solution of (1.1) follows from Palau and Pardo (2018, Proposition 1). Applying then Lemma A.3 from the appendix proves that this unique solution is actually a.s. finite and satisfies the desired moment bounds. Finally, the comparison property can be shown by following the proof of Dawson and Li (2012, Theorem 2.3) with the only difference that our conditions (3.a), (3.d) are weaker than those imposed in Dawson and Li (2012, Theorem 2.3). However, this does not affect the key argument. This completes the proof of this statement. \( \square \)

Let us remark that the constants appearing in the moment estimates can be computed explicitly. Below we provide the semimartingale characteristics for the process.

**Lemma 3.4.** Let \((b, \sigma, g_0, g_1)\) be admissible parameters and suppose that conditions (3.a) – (3.e) are satisfied, and that condition \((m)_\lambda\) holds for some \( \lambda > 0 \) or condition \((m)_{\log}\) is satisfied. Let \( \{X_t : t \geq 0\} \) be the unique strong solution to (1.1), and let \( h \) be a continuous bounded function on \( \mathbb{R} \) such that \( h(x) = x \) holds for \( |x| \leq 1 \). Then \( X \) is the unique semimartingale with characteristics \((B, C, K)\) with respect to \( h \) given by

\[
B_t = \int_0^t \tilde{b}(X_s) ds, \quad \tilde{b}(x) = b(x) - \int_{U_0} \tilde{h}(g_0(x, u)) \mu_0(du) + \int_{U_1} h(g_1(x, u)) \mu_1(du), \quad (3.3)
\]

\[
C_t = \int_0^t c(X_s) ds, \quad c(x) = \int_E \sigma(x, u)^2 \nu(du),
\]

\[
K(x, A) = \int_{U_0} 1_{A \setminus \{0\}}(g_0(x, u)) \mu_0(du) + \int_{U_1} 1_{A \setminus \{0\}}(g_1(x, u)) \mu_1(du),
\]

where \( \tilde{h}(x) = x - h(x) \).

Proof: If \( f \in C_b^2(\mathbb{R}) \), then an application of the Itô formula shows that \( f(X_t) = f(X_0) + A_t + \mathcal{M}_t \), where \((A_t)_{t \geq 0}\) is of locally finite variation and \((\mathcal{M}_t)_{t \geq 0}\) is a local martingale, respectively given by

\[
\mathcal{M}_t = \int_0^t \int_E \sigma(X_s, u) f'(X_s) W(ds, du) + \int_0^t \int_{U_0} (f(X_{s-} + g_0(X_{s-}, u)) - f(X_{s-})) \tilde{N}_0(ds, du)
\]

\+
\[
\int_0^t \int_{U_1} (f(X_{s-} + g_1(X_{s-}, u)) - f(X_{s-})) \tilde{N}_1(ds, du),
\]

\[
A_t = \int_0^t b(X_s) f'(X_s) ds + \frac{1}{2} \int_0^t \int_E \sigma(X_s, u)^2 f''(X_s) \nu(du) ds
\]

\+
\[
\int_0^t \int_{U_0} (f(X_s + g_0(X_s, u)) - f(X_s) - g_0(X_s, u)f'(X_s)) \mu_0(du) ds
\]

\+
\[
\int_0^t \int_{U_1} (f(X_s + g_1(X_s, u)) - f(X_s)) \mu_1(du) ds.
\]
A short computation shows that

$$\mathcal{A}_t = \int_0^t \tilde{b}(X_s) f'(X_s) ds + \frac{1}{2} \int_0^t \int_0^t \sigma(X_s, u)^2 f''(X_s) \kappa(du) ds$$

$$+ \int_0^t \int_{U_0} (f(X_s + g_0(X_s, u)) - f(X_s) - h(g_0(X_s, u)) f'(X_s)) \mu_0(du) ds$$

$$+ \int_0^t \int_{U_1} (f(X_s + g_1(X_s, u)) - f(X_s) - h(g_1(X_s, u)) f'(X_s)) \mu_1(du) ds$$

$$= \int_0^t \tilde{b}(X_s) f'(X_s) ds + \frac{1}{2} \int_0^t \int_E \sigma(X_s, u)^2 f''(X_s) \kappa(du) ds$$

$$+ \int_0^t \int_{U_0 \times U_1 \times \{0,1\}} \left( f(X_s + z) - f(X_s) - h(z) f'(X_s) \right) K(X_s, dz) ds,$$

where

$$G(x, u_0, u_1, l) = \mathbb{1}_{\{l=0\}} g_0(x, u) + \mathbb{1}_{\{l=1\}} g_1(x, u),$$

$$F(du_0, du_1, dl) = \mu_0(du_0) \delta_0(du_1) \delta_0(dl) + \delta_0(du_0) \mu_1(du_1) \delta_1(dl),$$

and

$$K(x, A) = \int_{U_0} \mathbb{1}_{A \setminus \{0\}} (g_0(x, u)) \mu_0(du) + \int_{U_1} \mathbb{1}_{A \setminus \{0\}} (g_1(x, u)) \mu_1(du)$$

$$= \int_{U_0 \times U_1 \times \{0,1\}} \mathbb{1}_{A \setminus \{0\}} (G(x, u_0, u_1, l)) F(du_0, du_1, dl).$$

The particular form of the characteristics is now a consequence of Kurtz (2011, Chapter II, Theorem 2.42), while the uniqueness of semimartingale characteristics is a consequence of Kurtz (2011, Chapter III, Theorem 2.26). This proves the assertion. 

In the following, we write \( \{X_t^x : t \geq 0\} \) for the unique strong solution of (1.1) to indicate that the process \( X_t \) starts with deterministic initial variable \( X_0 = x \geq 0 \). Arguing as in Li (2019) (see the proof of Theorem 1.1 therein) one can show that \( \{X_t^x : t \geq 0\} \) is a strong \((\mathcal{F}_t)_{t \geq 0}\)-Markov process with transition kernel \( P_t(x, dy) \). The adjoint action of the transition semigroup on \( \mathcal{P}(\mathbb{R}_{\geq 0}) \) is defined by

$$P_t^* \varrho(dy) = \int_{\mathbb{R}_{\geq 0}} P_t(x, dy) \varrho(dx), \quad t \geq 0, \varrho \in \mathcal{P}(\mathbb{R}_{\geq 0}).$$

By the Markov property we have that \( P_{t+s}^* = P_t^* P_s^* \) for all \( 0 \leq s \leq t \). Finally, in order to study the long-time behaviour we impose the following uniform dissipativity condition of the drift:

(3.f) It holds that \( \int_{U_1} |g_1(x, u)| \mu_1(du) < \infty \) for all \( x \geq 0 \) and there exists a constant \( A > 0 \) such that

$$b(y) - b(x) + \int_{U_1} (g_1(y, u) - g_1(x, u)) \mu_1(du) \leq -A(y - x)$$

holds for all \( x, y \geq 0 \) with \( x \leq y \).
Under the given conditions we are able to show that the corresponding Markov process is exponentially ergodic in the Wasserstein distance $W_1$.

**Theorem 3.5.** Let $(b,\sigma,g_0,g_1)$ be admissible parameters and suppose that conditions (3.a)–(3.f) hold, and that $(m)_\lambda$ holds for $\lambda = 1$. Then, for all $\varrho, \tilde{\varrho} \in \mathcal{P}_1(\mathbb{R}_{\geq 0})$, we have

$$W_1 \left( P^*_t \varrho, P^*_t \tilde{\varrho} \right) \leq e^{-At} W_1 \left( \varrho, \tilde{\varrho} \right), \quad t \geq 0. \quad (3.4)$$

In particular, there exists a unique invariant measure $\pi \in \mathcal{P}(\mathbb{R}_{\geq 0})$. Moreover, we have $\pi \in \mathcal{P}_1(\mathbb{R}_{\geq 0})$ and, for all $\varrho \in \mathcal{P}_1(\mathbb{R}_{\geq 0})$,

$$W_1 \left( P^*_t \varrho, \pi \right) \leq e^{-At} W_1 \left( \varrho, \pi \right), \quad t \geq 0.$$ 

**Proof:** First observe that $\{X^x_t : t \geq 0\}$ has finite first moment due to Lemma A.3.(a). Define for $n \in \mathbb{N}$ the stopping time $\tau_n(x) = \inf\{t \geq 0 : X^x_t \geq n\}$. In the proof of Lemma A.3.(a), we have shown that $\tau_n(x) \to \infty$ a.s. as $n \to \infty$ and that $(M^{n,x}_t)_{t \geq 0}$ is a martingale for each $n \in \mathbb{N}$, where

$$M^{n,x}_t = \int_0^{t \wedge \tau_n(x)} \int_E \sigma(X^x_s,u) W(ds,du) + \int_0^{t \wedge \tau_n(x)} \int_{U_0} g_0(X^x_{s-},u) \tilde{N}_0(ds,du).$$

Let $0 \leq x \leq y$ and define $\tau_n = \tau_n(x) \wedge \tau_n(y)$. Using the comparison principle, optional stopping, and then condition (3.f) we find that

$$\mathbb{E} \left[ |X^x_{t \wedge \tau_n} - X^y_{t \wedge \tau_n}| \right] = \mathbb{E}[X^y_{t \wedge \tau_n} - X^x_{t \wedge \tau_n}]$$

$$= y - x + \mathbb{E} \left[ \int_0^{t \wedge \tau_n} (\tilde{b}(X^x_s) - b(X^x_s))ds \right]$$

$$\leq |x - y| - \mathbb{E} \left[ \int_0^{t \wedge \tau_n} (X^y_s - X^x_s)ds \right]$$

$$= |x - y| - \mathbb{E} \left[ \int_0^{t \wedge \tau_n} |X^x_s - X^y_s|ds \right],$$

where $\tilde{b}(x) = b(x) + \int_{U_1} g_1(x,u)\mu_1(du)$. Let $D := \{t \geq 0 : \mathbb{P}[X^x_t = X^x_{t^-},X^y_t = X^y_{t^-}] = 1\}$. Taking the limit $n \to \infty$ and invoking $\tau_n \to \infty$ a.s., yields, due to cádlág sample paths of $X$, that for $t \in D$,

$$\mathbb{E}[|X^x_t - X^y_t|] = \liminf_{n \to \infty} \mathbb{E}[|X^x_{t \wedge \tau_n} - X^y_{t \wedge \tau_n}|]$$

$$\leq |x - y| - \mathbb{E} \left[ \int_0^t |X^x_s - X^y_s|ds \right].$$

For $t \notin D$, we find $D \supseteq t_n \downarrow t$ and then let $n \to \infty$ to obtain the above estimate also for $t \notin D$. Applying Gronwall’s lemma yields $\mathbb{E}[|X^x_t - X^y_t|] \leq |x - y|e^{-At}$ for $t \geq 0$. Let us now derive (3.4).

We denote by $\delta_x$ and $\delta_y$ the Dirac measure concentrated in $x$ and $y$, respectively. Assume $0 \leq x \leq y$. Since the joint distribution of $(X^x_t, X^y_t)$ belongs to $\mathcal{H}(P^*_t \delta_x, P^*_t \delta_y)$, we obtain

$$W_1 \left( P^*_t \delta_x, P^*_t \delta_y \right) \leq \mathbb{E}[|X^x_t - X^y_t|] \leq |x - y|e^{-At}, \quad t \geq 0. \quad (3.5)$$

Let $H$ be any coupling of $(\varrho, \tilde{\varrho})$ satisfying (2.1). Using the convexity of $W_1$ and (3.5), we get

$$W_1 \left( P^*_t \varrho, P^*_t \tilde{\varrho} \right) \leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} W_1 \left( P^*_t \delta_x, P^*_t \delta_y \right) H(dx,dy)$$

$$\leq e^{-At} \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} |x - y| H(dx,dy) = e^{-At} W_1 \left( \varrho, \tilde{\varrho} \right).$$
Next we prove the existence of an invariant measure \( \pi \in \mathcal{P}_1(\mathbb{R}_{\geq 0}) \). We fix any \( g \in \mathcal{P}_1(\mathbb{R}_{\geq 0}) \). Then, for \( k, l \in \mathbb{N} \) with \( k < l \),
\[
W_1(P_k^* \varrho, P_l^* \varrho) \leq \sum_{s=k}^{l-1} W_1(P_{s+1}^* \varrho, P_s^* \varrho) \leq \sum_{s=k}^{l-1} e^{-As} W_1(P_l^* \varrho, \varrho),
\]
where we have used the semigroup property of \( P_{s+1}^* \) together with (3.4). Since the right-hand side tends to zero as \( k, l \to \infty \), \( (P_k^* \varrho)_{k \in \mathbb{N}} \subset \mathcal{P}_1(\mathbb{R}_{\geq 0}) \) is a Cauchy sequence. As a consequence, there exists \( \pi \in \mathcal{P}_1(\mathbb{R}_{\geq 0}) \) such that \( W_1(P_k^* \varrho, \pi) \) converges to zero as \( k \to \infty \). To prove the invariance of \( \pi \), i.e., \( P_h^* \pi = \pi \), for all \( h > 0 \), let us fix \( h > 0 \). Using the semigroup property and (3.4) it follows
\[
W_1(P_h^* \pi, \pi) \leq W_1(P_h^* \pi, P_h^* P_h \varrho) + W_1(P_h^* P_h \varrho, P_h^* \varrho) + W_1(P_h^* \varrho, \pi) \\
\leq e^{-Ah} W_1(P_h^* \varrho, \pi) + e^{-Ah} W_1(P_h^* \varrho, \pi) + W_1(P_h^* \varrho, \pi),
\]
and the right-hand side tends to zero as \( k \to \infty \). Hence, we see that \( W_1(P_h^* \pi, \pi) = 0 \).

Finally, we prove the uniqueness of invariant measures. Let \( W_1^{\leq 1} \) be the Wasserstein distance given by (1.2) with \( d(x, y) = 1 \wedge |x - y| \) as introduced in Example 2.1.(d). Using the invariance of \( \pi, \hat{\pi} \), and the convexity of \( W_1^{\leq 1} \), for any \( H \in \mathcal{H}(\pi, \hat{\pi}) \), we derive
\[
W_1^{\leq 1} (\pi, \hat{\pi}) \leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} W_1^{\leq 1} (P_t^* \delta_x, P_t^* \delta_y) H(dx, dy) \\
\leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} \mathbb{E} [|X_t^x - X_t^y| \wedge 1] H(dx, dy) \\
\leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} (1 \wedge \mathbb{E} [|X_t^x - X_t^y|]) H(dx, dy) \\
\leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} (1 \wedge (|x - y|e^{-At})) H(dx, dy).
\]
By dominated convergence we see that the right-hand side vanishes as \( t \to \infty \). Consequently, \( W_1^{\leq 1} (\pi, \hat{\pi}) = 0 \) and this implies that \( \pi = \hat{\pi} \).

In our next result we prove that a similar ergodicity statement also holds true, if we replace \( (m)_1 \) either by \( (m)_\lambda \) with \( \lambda \in (0, 1) \) or by \( (m)_{log} \). However, as in such a case the process does not have finite first moment, we cannot directly use the above arguments. Our idea is to approximate the process by truncating the big jumps. In this way, the approximating process has finite first moments and hence previous results can be applied. Using the properties of the Wasserstein distance and passing to the limit where the truncation vanishes, we are able to derive the desired result formulated at the end of this section. Below we first prove that by truncating the big jumps, we obtain an approximation of the process.

**Proposition 3.6.** Let \( (b, \sigma, g_0, g_1) \) be admissible parameters, that conditions (3.a) – (3.e), \( (m)_{log} \) holds, and that
\[
x \mapsto g_0(x, u_0), \; \text{and} \; x \mapsto g_1(x, u_1)
\]
are continuous for \( \mu_0-a.a. \) \( u_0 \in U_0 \) and \( \mu_1-a.a. \) \( u_1 \in U_1 \). Finally, assume that there exists a sequence of subsets \( (U_k^1)_{k \geq 1} \) of \( U_1 \) such that \( |g_1(x, u)| \leq k \) holds for each \( x \geq 0, k \geq 1, u \in U_k^1 \), and \( U_k^1 \supset U_1 \). Define \( g_k^1(x, u) = 1_{U_k^1}(u)g_1(x, u) \) for \( x \geq 0 \) and \( u \in U_1 \). Then \( (b, \sigma, g_0, g_k^1) \) are admissible parameters which satisfy conditions (3.a) – (3.e), and \( (m)_1 \). Let \( \{X_k^t : t \geq 0\} \) be the associated sequence of strong solutions to (1.1) with \( g_1 \) replaced by \( g_k^1 \) but the same initial condition. Then \( X_k \Rightarrow X \) holds in law as \( k \to \infty \), where \( X \) is the unique strong solution to (1.1) with admissible parameters \( (b, \sigma, g_0, g_1) \).
Proof: It is not difficult to see that \((b, \sigma, g_0, g_1^k)\) are admissible and satisfy conditions \((3.a) - (3.e)\), and \((m)_1\). Let
\[
h(x) = \begin{cases} 
  x, & x \in [-1,1], \\
  1, & x \geq 1, \\
  -1, & x \leq -1,
\end{cases}
\]
and
\[
\tilde{h}(x) = x - h(x) = \begin{cases} 
  0, & x \in [-1,1], \\
  x - 1, & x \geq 1, \\
  x + 1, & x \leq -1.
\end{cases}
\]
Applying Lemma 3.4, we observe that \(X\) and \(X^k\) are semimartingales with characteristics \((B, C, K)\) with respect to the truncation function \(h\) given by (3.3), and \((B^k, C^k, K^k)\) given by
\[
B^k_t = \int_0^t \tilde{b}^k(X^k_s)ds, \quad \tilde{b}^k(x) = b(x) - \int_{U_0} \tilde{h}(g_0(x, u))\mu_0(du) + \int_{U_1} \tilde{h}(g_1^k(x, u))\mu_1(du),
\]
\[
C^k_t = \int_0^t c(X^k_s)ds, \quad c(x) = \int_E \sigma(x, u)^2 \kappa(du),
\]
\[
K^k(x, A) = \int_{U_0} 1_{A\neq \emptyset}(g_0(x, u))\mu_0(du) + \int_{U_1} 1_{A\neq \emptyset}(g_1^k(x, u))\mu_1(du).
\]
Finally define
\[
\tilde{c}(x) = c(x) + \int_{\mathbb{R}} h(y)^2 K(x, dy), \quad \tilde{c}^k(x) = c(x) + \int_{\mathbb{R}} h(y)^2 K^k(x, dy).
\]
The assertion now follows from Kurtz (2011, Chapter IX, Theorem 4.8) and the characterization of weak solutions to (1.1) in terms of semi-martingale characteristics (see Kurtz (2011, Chapter III, Theorem 2.26)), provided we can show the following set of conditions:

(a) \(\lim_{a \to \infty} \sup_{x \in [0, R]} K(x, [-a, a]^c) = 0\) for each \(R > 0\);

(b) The functions \(b(x) \mapsto \tilde{b}(x), \tilde{c}(x), \int_{\mathbb{R}} f(y)K(x, dy)\) are continuous for each continuous and bounded function \(f\) satisfying \(|f(y)| \leq C_f(1 + y^2)\) for some constant \(C_f > 0\);

(c) The convergence \(\tilde{b}^k \to \tilde{b}, \tilde{c}^k \to \tilde{c}^k, \int_{\mathbb{R}} f(y)K^k(\cdot, dy) \to \int_{\mathbb{R}} f(y)K(\cdot, dy)\) hold locally uniformly for each continuous and bounded function \(f\) satisfying \(|f(y)| \leq C_f(1 + y^2)\), where \(C_f > 0\) is some constant.

Condition (a) follows from \((m)_{log}\) and the estimates
\[
K(x, [-a, a]^c) = \mu_0(\{|g_0(x, \cdot)| > a\}) + \mu_1(\{|g_1(x, \cdot)| > a\})
\]
\[
\leq \frac{1}{a} \int_{U_0} 1_{\{|g_0(x, u)| > 1\}} |g_0(x, u)|\mu_0(du)
\]
\[
+ \frac{1}{\log(1 + a)} \int_{U_1} 1_{\{|g_1(x, u)| > 1\}} \log(1 + |g_1(x, u)|)\mu_1(du)
\]
\[
\leq \frac{K_{log}(2 + x)}{a} + \frac{K_{log}(2 + x)}{\log(1 + a)},
\]
where \(a > 1\). For condition (b), we let \((x_n)_{n \in \mathbb{N}} \subset \mathbb{R}_{\geq 0}\) such that \(x_n \to x\). Then
\[
|\tilde{b}(x_n) - \tilde{b}(x)| \leq |b(x_n) - b(x)| + \int_{U_0} |\tilde{h}(g_0(x_n, u)) - \tilde{h}(g_0(x, u))|\mu_0(du)
\]
\[
+ \int_{U_1} |h(g_1(x_n, u)) - h(g_1(x, u))|\mu_1(du)
\]
\[
\leq J_1 + J_2 + J_3.
\]
The first term \(J_1\) converges to zero due to the continuity of \(b\). The second term tends to zero due to (3.6), the continuity of \(\tilde{h}\), and the dominated convergence theorem. The latter one is applicable in view of \(|\tilde{h}(g_0(x_n, u))| \leq 1_{\{|g_0(x_n, u)| > 1\}}(|g_0(x_n, u)| + 1) \leq 1_{\{|g_0(u, j)| > 1\}} 2g_0(j, u)\) and condition (3.d),
Similarly, using conditions (3.d), i.e.,
\[ \int_{U_0} \mathbb{1}_{\{g_0(j, u) > 1\}} g_0(j, u) \mu_0(du) \leq L(j) < \infty, \]
where \( j \in \mathbb{N} \) is such that \( x_n, x \leq j \) for each \( n \in \mathbb{N} \). For the last term \( J_3 \) we use condition (3.b) to find that
\[
J_3 \leq \int_{U_1} |g_1(x_n, u) - g_1(x, u)| \mu_1(du) \leq r_j(\|x_n - x\|),
\]
which tends to zero due to the continuity of \( r_j \). Next, for \( \tilde{c} \) we obtain
\[
|\tilde{c}(x_n) - \tilde{c}(x)| \leq \int_E |\sigma(x_n, u)|^2 - \sigma(x, u)^2| \kappa(du)
+ \int_{U_0} |h(g_0(x_n, u))^2 - h(g_0(x, u))^2| \mu_0(du)
+ \int_{U_1} |h(g_1(x_n, u))^2 - h(g_1(x, u))^2| \mu_1(du)
= I_1 + I_2 + I_3.
\]
For the first term we use the Hölder inequality and then condition (3.c) to get
\[
I_1 \leq \int_E (|\sigma(x_n, u)| + |\sigma(x, u)|)|\sigma(x_n, u) - \sigma(x, u)| \kappa(du)
\leq \left( \int_E (|\sigma(x_n, u)| + |\sigma(x, u)|)^2 \kappa(du) \right)^{1/2} \left( \int_E |\sigma(x_n, u) - \sigma(x, u)|^2 \kappa(du) \right)^{1/2}
\leq (2K_1(2 + x_n)^2 + 2K_1(2 + x)^2)^{1/2} \sqrt{A_1} |x_n - x| \to 0.
\]
Similarly, using conditions (3.d), \( |h(x)| \leq 1 \wedge |x| \), and \( |h(x) - h(y)| \leq 2 \wedge |x - y| \leq 2(1 \wedge |x - y|) \) we find that
\[
I_2 \leq \left( \int_{U_0} (2h(g_0(x_n, u))^2 + 2h(g_0(x, u))^2) \mu_0(du) \right)^{1/2}
\cdot \left( \int_{U_0} |h(g_0(x_n, u)) - h(g_0(x, u))|^2 \mu_0(du) \right)^{1/2}
\leq 2\sqrt{2} \left( \int_{U_0} (1 \wedge |g_0(x_n, u)|^2 + 1 \wedge |g_0(x, u)|^2) \mu_0(du) \right)^{1/2}
\cdot \left( \int_{U_0} 1 \wedge |g_0(x_n, u) - g_0(x, u)|^2 \mu_0(du) \right)^{1/2}
\leq 2\sqrt{2} \left( \int_{U_0} (|g_0(x_n, u)| \wedge |g_0(x_n, u)|^2 + |g_0(x, u)| \wedge |g_0(x, u)|^2) \mu_0(du) \right)^{1/2}
\cdot \left( \int_{U_0} |g_0(x_n, u) - g_0(x, u)| \wedge |g_0(x_n, u) - g_0(x, u)|^2 \mu_0(du) \right)^{1/2}
\leq 2\sqrt{2} (L(x_n) + L(x))^{1/2} \sqrt{B_1} |x_n - x|,
\]
which tends to zero as \( n \to \infty \). Similarly, for \( I_3 \) we find by conditions (3.a) and (3.e) that

\[
I_3 \leq \left( \int_{U_1} \frac{2h(g_1(x_n, u))^2 + 2h(g_1(x, u))^2}{\mu_1(du)} \right)^{1/2} \cdot \left( \int_{U_1} \left| h(g_1(x, u)) - h(g_1(x, u)) \right|^2 \mu_1(du) \right)^{1/2}
\leq 2\sqrt{2} \left( \int_{U_1} (1 \wedge |g_1(x_n, u)|^2 + 1 \wedge |g_1(x, u)|^2) \mu_1(du) \right)^{1/2} \cdot \left( \int_{U_1} 1 \wedge |g_1(x_n, u) - g_1(x, u)|^2 \mu_1(du) \right)^{1/2}
\leq 2\sqrt{2} \sqrt{K_0((2 + x_n) + (2 + x))r_j(|x_n - x|)}
\]

which tends to zero as \( n \to \infty \). Finally, we find that

\[
\left| \int_{\mathbb{R}} f(y)K(x_n, dy) - \int_{\mathbb{R}} f(y)K(x, dy) \right| \leq \int_{U_0} (f(g_0(x_n, u)) - f(g_0(x, u)))\mu_0(du)
+ \int_{U_1} (f(g_1(x_n, u)) - f(g_1(x, u)))\mu_1(du).
\]

For the integral against \( \mu_0 \) we use (3.6) combined with the dominated convergence theorem, which is applicable due to \( |f(g_0(x_n, u))| \leq C_f(1 \wedge |g_0(x_n, u)|^2) \leq C_f(1 \wedge |g_0(j, u)|^2) \) and condition (3.d), i.e.,

\[
\int_{U_0} (1 \wedge |\overline{g}_0(j, u)|^2)\mu_0(du) \leq \int_{U_0} (|\overline{g}_0(j, u)| \wedge |\overline{g}_0(j, u)|^2)\mu_0(du) \leq L(j) < \infty.
\]

For the second term we use again the dominated convergence theorem, which is applicable due to (3.6) and condition (3.a), since \( |f(g_1(x_n, u))| \leq C_f(1 \wedge |g_1(x_n, u)|^2) \leq C_f(1 \wedge |g_1(x, u)|^2) \leq C_f(1 \wedge |\overline{g}_1(j, u)|) \) and \( \int_{U_1} (1 \wedge |\overline{g}_1(j, u)|)\mu_1(du) \leq K_0(2 + j) < \infty \). Thus we have shown that \( \int_{\mathbb{R}} f(y)K(x_n, dy) \mapsto \int_{\mathbb{R}} f(y)K(x, dy) \), which completes the proof of property (b). To prove property (c), let us first observe that

\[
|\tilde{b}^k(x) - \tilde{b}(x)| \leq \int_{U_1} \left( h(g_1^k(x, u)) - h(g_1(x, u)) \right) \mu_1(du)
= \int_{U_1 \setminus U_1^k} h(g_1(x, u))\mu_1(du)
\leq \int_{U_1 \setminus U_1^k} (1 \wedge |g_1(x, u)|)\mu_1(du)
\leq \int_{U_1 \setminus U_1^k} (1 \wedge |\overline{g}_1(j, u)|)\mu_1(du),
\]
where \( j \in \mathbb{N} \) is such that \( x \in [0, j] \). The convergence to zero is now a direct consequence of \( \mathcal{U}_t^k \nearrow \mathcal{U}_1 \), condition (3.a), and the dominated convergence theorem. For the second term we observe that

\[
|\tilde{c}^k(x) - \tilde{c}(x)| \leq \int_{\mathcal{U}_1 \setminus \mathcal{U}_1^k} h(g_1(x, u))^2 \mu_1(du) \\
\leq \int_{\mathcal{U}_1 \setminus \mathcal{U}_1^k} (1 \wedge |g_1(x, u)|^2) \mu_1(du) \\
\leq \int_{\mathcal{U}_1 \setminus \mathcal{U}_1^k} (1 \wedge |\tilde{g}_1(j, u)|) \mu_1(du).
\]

This shows that \( \tilde{c}^k \to \tilde{c} \) locally uniformly in \( x \). Finally, let \( f \) be a continuous and bounded function satisfying \( |f(y)| \leq C_f (1 \wedge |y|^2) \). Then

\[
\left| \int_{\mathbb{R}} f(y) K^k(x, dy) - \int_{\mathbb{R}} f(y) K(x, dy) \right| = \left| \int_{\mathcal{U}_1} (f(g_1^k(x, u)) - f(g_1(x, u))) \mu_1(du) \right| \\
= \left| \int_{\mathcal{U}_1 \setminus \mathcal{U}_1^k} f(g_1(x, u)) \mu_1(du) \right| \\
\leq C_f \int_{\mathcal{U}_1 \setminus \mathcal{U}_1^k} (1 \wedge |\tilde{g}_1(j, u)|) \mu_1(du).
\]

This completes the proof of property (c) and hence completes the proof of this Proposition. \( \square \)

Remark 3.7. By adapting the methods from Dawson and Li (2012), it should be possible to derive a stronger statement where \( X \) and the approximation \( X^k \) are both realized on the same probability space and the convergence holds at least in the sense that \( \mathbb{E}[1 \wedge |X^k - X|] \) converges to zero. Since we do not need such a stronger statement, we leave these details for the interested reader.

Below we introduce a localized version of the dissipativity condition (3.f).

(3.g) There exists a sequence of subsets \( (\mathcal{U}_1^k)_{k \geq 1} \) of \( \mathcal{U}_1 \) such that \( |g_1(x, u)| \leq k \) holds for each \( x \geq 0, k \geq 1 \) and \( u \in \mathcal{U}_1^k \), and \( \mathcal{U}_1^k \nearrow \mathcal{U}_1 \). Moreover, there exists a constant \( A > 0 \) such that

\[
b(y) - b(x) + \int_{\mathcal{U}_1^k} (g_1(y, u) - g_1(x, u)) \mu_1(du) \leq -A(y - x)
\]

holds for all \( 0 \leq x \leq y \) and \( k \geq 1 \).

Now we are prepared for our second main result of this section.

Theorem 3.8. Let \((b, \sigma, g_0, g_1)\) be admissible parameters. Suppose that conditions (3.a) – (3.e), (3.g), and (3.6) hold. Then the following assertions hold:

(a) If \((m)_\lambda\) holds for some \( \lambda \in (0, 1) \), then

\[
W_{\lambda'}(P_{t}^* \varrho, P_{t}^* \bar{\varrho}) \leq e^{-\lambda' t} W_{\lambda}(\varrho, \bar{\varrho}), \quad t \geq 0
\]

holds for each \( \lambda' \in (0, \lambda) \). In particular, there exists a unique invariant measure \( \pi \in \mathcal{P}(\mathbb{R}_{\geq 0}) \), this measure belongs to \( \mathcal{P}_{\lambda'}(\mathbb{R}_{\geq 0}) \), and for all \( \varrho, \bar{\varrho} \in \mathcal{P}_{\lambda'}(\mathbb{R}_{\geq 0}) \) one has

\[
W_{\lambda'}(P_{t}^* \varrho, \pi) \leq e^{-\lambda' t} W_{\lambda'}(\varrho, \pi), \quad t \geq 0.
\]

(b) If \((m)_{\log}\) holds, then for all \( \varrho, \bar{\varrho} \in \mathcal{P}(\mathbb{R}_{\geq 0}) \) one has \( \lim_{t \to \infty} W_{t}^{\leq 1}(P_{t}^* \varrho, P_{t}^* \bar{\varrho}) = 0 \), and there exists a constant \( c > 0 \) such that

\[
W_{t}^{\leq 1}(P_{t}^* \varrho, P_{t}^* \bar{\varrho}) \leq c \left( e^{-At} W_{\log}(\varrho, \bar{\varrho}) + \min\{e^{-At}, W_{\log}(\varrho, \bar{\varrho})\} \right).
\]
In particular, there exists a unique invariant measure \( \pi \), this measure belongs to \( \mathcal{P}_{\log}(\mathbb{R}_{\geq 0}) \), and for all \( \varrho \in \mathcal{P}(\mathbb{R}_{\geq 0}) \) one has \( \lim_{t \to \infty} W_{1}^{\leq 1}(P_{t}^{*} \varrho, \pi) = 0 \) and
\[
W_{1}^{\leq 1}(P_{t}^{*} \varrho, \pi) \leq c \left( e^{-At} W_{\log}(\varrho, \pi) + \min\{e^{-At}, W_{\log}(\varrho, \pi)\} \right).
\]

**Proof:** Let \( (P_{t}^{*})_{t \geq 0} \) be the transition semigroup associated with \( \{X_{t}^{x,k} : t \geq 0\} \), and let \( (P_{t}^{*})_{t \geq 0} \) be the transition semigroup associated with the approximation \( \{X_{t}^{x,k} : t \geq 0\} \) constructed in Proposition 3.6. Then \( \{X_{t}^{x,k} : t \geq 0\} \) satisfies all conditions of Theorem 3.5.

(a) Lemma 2.2 and Theorem 3.5 applied to the approximating process \( \{X_{t}^{x,k} : t \geq 0\} \) gives
\[
W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \leq \left( W_{1}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \right)^{\lambda} \leq e^{-\lambda X_{t}^{\rho} |x - y|^{\lambda}}. \]
This yields
\[
W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \leq W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{x}) + W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) + W_{\lambda}(P_{t}^{*} \delta_{y}, P_{t}^{*} \delta_{y}) \leq W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{x}) + e^{-\lambda X_{t}^{\rho} |x - y|^{\lambda}} + W_{\lambda}(P_{t}^{*} \delta_{y}, P_{t}^{*} \delta_{y}).
\]

Let \( D := \{ t \geq 0 : \mathbb{P}[X_{t}^{\rho} = X_{t}^{-}] = 1 \} \). Since the process \( X \) has càdlàg paths, the set \( \mathbb{R}_{\geq 0} \setminus D \) is at most countable (see Ethier and Kurtz (1986, Chapter 3, Lemma 7.7)). Moreover, since \( X^{k} \Rightarrow X \), the characterization of convergence in the Skorohod space implies that \( X_{t}^{x,k} \Rightarrow X_{t}^{\rho} \) holds for all \( t \in D \) (see Ethier and Kurtz (1986, Chapter 3, Theorem 7.8)). Since \( \sup_{k \geq 1} \mathbb{E}[|X_{t}^{k}|^{\lambda}] < \infty \) we conclude that \( X_{t}^{x,k} \Rightarrow X_{t}^{\rho} \) also holds in \( W_{\lambda} \) for \( t \in D \). Hence taking the limit \( k \to \infty \) gives
\[
W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \leq e^{-\lambda X_{t}^{\rho} |x - y|^{\lambda}}. \]
Now let \( t \in \mathbb{R}_{\geq 0} \setminus D \), then using Ethier and Kurtz (1986, Chapter 3, Theorem 7.8.(a)) we find a sequence \( (t_{n})_{n \in \mathbb{N}} \subseteq \mathbb{R}_{\geq 0} \setminus D \) such that \( t_{n} \to t, t_{n} > t \). Then
\[
W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \leq W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{x}) + W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) + W_{\lambda}(P_{t}^{*} \delta_{y}, P_{t}^{*} \delta_{y}) \leq W_{\lambda}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{x}) + e^{-\lambda X_{t}^{\rho} |x - y|^{\lambda}} + W_{\lambda}(P_{t}^{*} \delta_{y}, P_{t}^{*} \delta_{y}).
\]

It is not difficult to show that the first and last term tend to zero as \( n \to \infty \). This proves the assertion.

(b) In this case we find that
\[
W_{1}^{\leq 1}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \leq 1 + \mathbb{E}[|X_{t}^{x,k} - X_{t}^{y,k}|] \leq \min\{1, e^{-At} |x - y|\}
\]
and hence
\[
W_{1}^{\leq 1}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \leq W_{1}^{\leq 1}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{x}) + \min\{1, e^{-At} |x - y|\} + W_{1}^{\leq 1}(P_{t}^{*} \delta_{y}, P_{t}^{*} \delta_{y}).
\]

Since \( X_{t}^{x,k} \Rightarrow X_{t}^{\rho} \), we find that \( W_{1}^{\leq 1}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{x}) \to 0 \) as \( k \to \infty \) for \( t \in D \). Hence taking the limit \( k \to \infty \) gives \( W_{1}^{\leq 1}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \leq \min\{1, e^{-At} |x - y|\} \) first for \( t \in D \), and then using the same arguments as in part (a) also for all \( t \geq 0 \). Using now that \( 1 \wedge \alpha \leq \log(2) - 1 \log(1 + a) \) for all \( a \geq 0 \), combined with the inequality
\[
\log(1 + a \cdot d) \leq C \min\{a, \log(1 + d)\} + Ca \log(1 + d), \tag{3.7}
\]
where \( C > 0 \) is a constant and \( a, d \geq 0 \) (see Friesen et al. (2020b, Lemma A.5)), we find for some new constant \( C > 0 \)
\[
W_{1}^{\leq 1}(P_{t}^{*} \delta_{x}, P_{t}^{*} \delta_{y}) \leq C (e^{-At} \log(1 + |x - y|) + \min\{e^{-At}, \log(1 + |x - y|)\})
\]
This readily implies
\[
W_{1}^{\leq 1}(P_{t}^{*} \varrho, P_{t}^{*} \varrho) \leq c (e^{-At} W_{\log}(\varrho, \varrho) + \min\{e^{-At}, W_{\log}(\varrho, \varrho)\})
\]

The second part of the assertion can be now deduced by a standard Cauchy argument similarly to the proof of Friesen et al. (2020b, Lemma 7.2). □
At this point it is worthwhile to mention that although condition (3.3) (or (3.4)) seems to be restrictive, there are abundant classes of processes fulfilling it. In the subsequent sections we discuss the particular classes of continuous-state branching processes with immigration and their extensions to nonlinear branching mechanisms or Lévy random environments.

However, condition (3.4) requires a global estimate valid for all $x, y \geq 0$ which essentially rules out models with strongly non-linear drifts such as $b(x) = x - x^3$. Assuming that the coefficients in front of the noise terms are non-degenerate, it was shown in Douc et al. (2009); Eberle et al. (2019); Kulik (2009); Veretennikov (1987) that already a local version of condition (3.4) is sufficient for the exponential ergodicity. Thus one may hope to replace the global drift condition (3.4) by a local drift condition, provided that the noise terms are non-degenerate in a certain sense. However, our applications of interest studied in the subsequent sections do not satisfy such non-degeneracy conditions, but still satisfy the global drift condition (3.4). Therefore, we focus in this work on this specific setting.

4. Branching processes

4.1. Nonlinear branching processes. Let $\gamma_0, \gamma_1, \gamma_2$ be continuous functions on $\mathbb{R}_{\geq 0}$ satisfying $\gamma_0(0) \geq 0$, $\gamma_1, \gamma_2 \geq 0$, $\gamma_0(0) = \gamma_2(0) = 0$, and let $m, \nu$ be Borel measures on $\mathbb{R}_{\geq 0}$ satisfying $m(\{0\}) = \nu(\{0\}) = 0$ and the moment condition

$$\int_{\mathbb{R}_{\geq 0}} z \wedge z^2 m(dz) + \int_{\mathbb{R}_{\geq 0}} 1 \wedge z \nu(dz) < \infty. \quad (4.1)$$

A CNBI process is obtained as the unique $\mathbb{R}_{\geq 0}$-valued strong solution of

$$X_t = X_0 + \int_0^t \gamma_0(X_s) \, ds + \int_0^t \int_0^\infty 1_{\{u \leq \gamma_1(X_s)\}} W(ds, du) + \int_0^t \int_0^\infty 1_{\{u \leq \gamma_2(X_{s-})\}} z \tilde{N}_0(ds, dz, du) + \int_0^t \int_0^\infty z N_1(ds, dz), \quad (4.2)$$

where $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$ is a stochastic basis with the usual conditions, $W(dt, du)$ is an $(\mathcal{F}_t)_{t \geq 0}$-Gaussian white noise with intensity measure $dt du$ on $\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$, $\tilde{N}_0(dt, dz, du)$ and $N_1(dt, dz)$ are $(\mathcal{F}_t)_{t \geq 0}$-Poisson random measures with intensity measures $dt m(dz) du$ on $\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$ and $dt \nu(dz)$ on $\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$. Further, it is assumed that $W(dt, du)$, $\tilde{N}_0(dt, dz, du)$, and $N_1(dt, dz)$ are mutually independent and $\tilde{N}_0(dt, dz, du) = N_0(dt, dz, du) - dt m(dz) du$ denotes the corresponding compensated Poisson random measure.

Continuous-state nonlinear branching processes (CNB process) were recently introduced and studied by Li et al. (2019) and correspond to (4.2) where $\nu = 0$, i.e., to absence of immigration. In this paper we add to the CNB process a general immigration mechanism and therefore call it a continuous-state nonlinear branching process with immigration (CNBI process). Below we apply our main results from Section 3 to the case of CNBI and CBI processes which leads to new insights on the existence, uniqueness of invariant measures as well as convergence of transition probabilities towards the unique invariant measure.

**Theorem 4.1.** Suppose that the functions $\gamma_i$, $i = 0, 1, 2$, satisfy the following:

(i) $\gamma_0(0) \geq 0$, $\gamma_1, \gamma_2 \geq 0$ are continuous, and $\gamma_2$ is nondecreasing;

(ii) there exists a constant $K \geq 0$ such that for all $x \geq 0$,

$$\gamma_0(x) \leq K(1 + x), \quad \gamma_1(x) + \gamma_2(x) \leq K(1 + x^2);$$

(iii) for each $j \geq 1$ there exists a constant $c_j > 0$ such that, for all $0 \leq x, y \leq j$,

$$|\gamma_0(x) - \gamma_0(y)| + |\gamma_1(x) - \gamma_1(y)| + |\gamma_2(x) - \gamma_2(y)| \leq c_j |x - y|.$$

(iv) It holds that $\int_{|z| > 1} \log(1 + z) \nu(dz) < \infty$. 

Then there exists a unique non-negative strong solution of (4.2), and this solution has the comparison property.

Proof: The assertion is a direct consequence of Theorem 3.3 applied to the following choices:

- \( E = \mathbb{R}_{\geq 0} \), \( U_0 = \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \), \( U_1 = \mathbb{R}_{\geq 0} \);
- \( b(x) = b_1(x) = \gamma_0(x) \), \( \sigma(x, u) = 1\{u \leq \gamma_1(x)\} \), \( g_0(x, z, u) = z1\{u \leq \gamma_2(x)\} \); \( g_1(x, z) = z \);
- \( \pi(\text{d}u) = \text{d}u \), \( \mu_0(\text{d}z, \text{d}u) = m(\text{d}z)\text{d}u \), \( \mu_1(\text{d}z) = \nu(\text{d}z) \).

Indeed, it is routine to check the conditions (3.a)-(3.e), and \( (m)_{\log} \) is clearly true because of assumption (iv). This proves the assertion.

As a consequence of Theorem 4.1 the unique solution to (4.2) is a strong \((\mathcal{F}_t)_{t \geq 0}\)-Markov process which is the desired CNBI process. Let \( \{P_t : t \geq 0\} \) be its transition semigroup and \( \{P_t^* : t \geq 0\} \) be the dual semigroup. Ergodicity of the CNBI process in different Wasserstein distances is obtained below.

**Theorem 4.2.** Suppose that conditions (i) – (iii) of Theorem 4.1 are satisfied and assume that there exists a constant \( A > 0 \) such that

\[
\gamma_0(y) - \gamma_0(x) \leq -A(y - x), \quad 0 \leq x \leq y;
\]

Then the following assertions hold:

(a) If \( \int_{\{z > 1\}} \log(1 + z)\nu(\text{d}z) < \infty \) and \( \gamma_2(x) \leq K(1 + x) \) hold for all \( x \geq 0 \), then for all \( \varrho, \tilde{\varrho} \in \mathcal{P}(\mathbb{R}_{\geq 0}) \) one has \( \lim_{t \to \infty} W_1^{\leq 1}(P_t^\varrho, P_t^*\tilde{\varrho}) = 0 \), and there exists a constant \( c > 0 \) such that

\[
W_1^{\leq 1}(P_t^\varrho, P_t^*\tilde{\varrho}) \leq c \left( e^{-At}W_{\log}(\varrho, \tilde{\varrho}) + \min\{e^{-At}, W_{\log}(\varrho, \tilde{\varrho})\} \right).
\]

In particular, there exists a unique invariant measure \( \pi \), this measure belongs to \( \mathcal{P}_{\log}(\mathbb{R}_{\geq 0}) \), and for all \( \varrho \in \mathcal{P}(\mathbb{R}_{\geq 0}) \) one has \( \lim_{t \to \infty} W_1^{\leq 1}(P_t^\varrho, \pi) = 0 \) and

\[
W_1^{\leq 1}(P_t^\varrho, \pi) \leq c \left( e^{-At}W_{\log}(\varrho, \pi) + \min\{e^{-At}, W_{\log}(\varrho, \pi)\} \right).
\]

(b) If there exists \( \lambda \in (0, 1) \) such that \( \int_{\{z > 1\}} z^\lambda\nu(\text{d}z) < \infty \) and \( \gamma_2(x) \leq K(1 + x)^\lambda \) for all \( x \geq 0 \), then

\[
W_{\lambda'}(P_t^\varrho, P_t^*\tilde{\varrho}) \leq e^{-\lambda'At}W_{\lambda'}(\varrho, \tilde{\varrho}), \quad t \geq 0
\]

holds for each \( \lambda' \in (0, \lambda) \). In particular, there exists a unique invariant measure \( \pi \in \mathcal{P}(\mathbb{R}_{\geq 0}) \), this measure belongs to \( \mathcal{P}_{\lambda'}(\mathbb{R}_{\geq 0}) \), and for all \( \varrho \in \mathcal{P}_{\lambda'}(\mathbb{R}_{\geq 0}) \) one has

\[
W_{\lambda'}(P_t^\varrho, \pi) \leq e^{-\lambda'At}W_{\lambda'}(\varrho, \pi), \quad t \geq 0.
\]

(c) If \( \int_{\{z > 1\}} \nu(\text{d}z) < \infty \) and \( \gamma_2(x) \leq K(1 + x) \) for all \( x \geq 0 \), then

\[
W_1(P_t^\varrho, P_t^*\tilde{\varrho}) \leq e^{-At}W_1(\varrho, \tilde{\varrho}), \quad t \geq 0.
\]

In particular, there exists a unique invariant measure \( \pi \in \mathcal{P}(\mathbb{R}_{\geq 0}) \), this measure belongs to \( \mathcal{P}_1(\mathbb{R}_{\geq 0}) \), and for all \( \varrho \in \mathcal{P}_1(\mathbb{R}_{\geq 0}) \) one has

\[
W_1(P_t^\varrho, \pi) \leq e^{-At}W_1(\varrho, \pi), \quad t \geq 0.
\]

Proof: The assertion follows from either Theorem 3.5 or Theorem 3.8. Indeed, choosing \( U_1^k = [0, k] \), for (a) condition \((m)_{\log} \) is satisfied, (b) implies \((m)_{\lambda} \), (c) implies \((m)_1 \).

We conclude this section with the following example for \( \gamma_0, \gamma_1, \gamma_2 \).

**Example 4.3.** Theorem 4.2 is applicable for the particular choice:

- \( \gamma_0(x) = \beta - bx \) where \( \beta \geq 0 \) and \( b > 0 \) are constants;
- \( \gamma_1(x) = x^\alpha \) with \( \alpha \in [1, 2] \);
- \( \gamma_2(x) = x \) or \( \gamma_2(x) = x \wedge x^\delta \) with \( \delta \in [0, 1] \).
Note that the particular choice $\gamma_0(x) = x - x^3$ would not satisfy the condition (4.3) and hence our result from Section 3 is not applicable in this case. The treatment of all these cases requires different methods and is left for future research.

4.2. Continuous-state branching processes with immigration. Next we study the special case where $\gamma_0, \gamma_1, \gamma_2$ are affine linear, i.e., the case of CBI processes in more detail. Namely, we suppose that $\gamma_0(x) = \beta + bx, \gamma_1(x) = \sigma^2 x,$ and $\gamma_2(x) = x.$

In this case the corresponding process obtained from (4.2) is a continuous-state branching processes with immigration (CBI processes) as first introduced by Feller (1951) and Jiřina (1958) and then developed by Kawazu and Watanabe (1971). For a detailed treatment of CBI processes encompassing a concise introduction we refer to the monographs of Li (2011).

Following the notion on CBI processes, we call $(\beta, b, \sigma, m, \nu)$ admissible parameters if $\beta \geq 0, b \in \mathbb{R}, \sigma \geq 0, m$ and $\nu$ are Borel measures on $\mathbb{R}_{\geq 0}$ satisfying $m(\{0\}) = \nu(\{0\}) = 0,$ and (4.1). CBI processes have the crucial property that their Laplace transform can be explicitly expressed in terms of a solution to a ordinary differential equations (the so-called Riccati equation). Namely, for $\lambda \geq 0,$ define the branching mechanism
\[
\phi(\lambda) = b\lambda + \frac{1}{2} \sigma^2 \lambda^2 + \int_0^\infty \left( e^{-\lambda z} - 1 + \lambda z \right) m(dz),
\]
and immigration mechanism
\[
\psi(\lambda) = \beta \lambda + \int_0^\infty \left( 1 - e^{-\lambda z} \right) \nu(dz).
\]

Then the transition kernel of the CBI process $\{P_t: t \geq 0\}$ has the Laplace transform
\[
\int_0^\infty e^{-\lambda z} P_t(x, dz) = \exp \left( -x v_t(\lambda) - \int_0^t \psi(v_s(\lambda)) ds \right), \quad x, \lambda \geq 0,
\]
where $t \mapsto v_t(\lambda)$ is the unique nonnegative solution of the ODE
\[
\frac{\partial}{\partial t} v_t(\lambda) = -\phi(\lambda), \quad v_0(\lambda) = \lambda.
\]

Pinsky (1972) announced the existence of a limit distribution for subcritical $(b > 0)$ CBI processes under the condition
\[
\int_{\{z > 1\}} \log(z) \nu(dz) < \infty.
\]
It was shown subsequently in Li (2011, Theorem 3.20 and Corollary 3.21) and Keller-Ressel (2011, Theorem 3.16) that for subcritical CBI processes condition (4.6) is equivalent to the weak convergence of process towards a limiting distribution, which is the unique invariant measure. Properties of this distribution were investigated in Keller-Ressel and Mijatović (2012) while a multidimensional version of Pinsky’s result was recently studied in Jin et al. (2020). For the more general class of affine processes on the canonical state space, which includes CBI processes, convergence in the Wasserstein distances $W_\lambda$ with $\lambda \in (0, 1]$ and $W_{\log}$ was recently shown in Friesen et al. (2020b, Theorem 1.5). Thus, our results from Theorem 4.2 are close to optimal. Below we focus on convergence with respect to the stronger total variation distance.

Based on the approach of Meyn and Tweedie, the exponential ergodicity in the total variation distance was for particular examples studied in Jin et al. (2019, 2016a,b); Masuda (2007). Using the construction of a successful coupling, the exponential ergodicity in the total variation distance for a subcritical CBI process (that is $b > 0$) with admissible parameters $(b, \beta, \sigma, m, \nu \equiv 0)$ was recently shown in Li and Ma (2015), provided Grey’s condition is satisfied, i.e.,
Here and below we let processes with non-vanishing jump measure Our next theorem extends the result of Li and Ma (2015, Theorem 2.4 and Theorem 2.5) to CBI optimal coupling of $P$ (2015, Theorem 2.5). where the last inequality follows from Li and Ma (2015, Theorem 2.4) and the proof of Li and Ma particular, there exists

$\theta > 0$ such that $\phi(\lambda) > 0$ for $\lambda > \theta$ and

$$\int_\theta^\infty \phi(\lambda)^{-1}d\lambda < \infty.$$ Our next theorem extends the result of Li and Ma (2015, Theorem 2.4 and Theorem 2.5) to CBI processes with non-vanishing jump measure $\nu$ for immigration.

**Theorem 4.4.** Let $(\beta,b,\sigma,m,\nu)$ be admissible parameters with $b > 0$ and suppose that (4.6) and (4.a) are satisfied. Let $\{P_t : t \geq 0\}$ be the transition kernel given by (4.4) and let $\pi$ be the unique invariant distribution. Then the following holds:

(a) There exists a constant $C > 0$ such that

$$\|P_t(x,\cdot) - P_t(y,\cdot)\|_{TV} \leq C \min \left\{1, e^{-bt}|x-y|\right\}.$$ In particular, $\{P_t : t \geq 0\}$ has the strong Feller property.

(b) There exists a constant $C > 0$ such that, for all $\varrho \in \mathcal{P}_{\log}(\mathbb{R}_{\geq 0})$ and $t \geq 0$, we have

$$\|P_t^* \varrho - \pi\|_{TV} \leq C \min \{e^{-bt}, W_{\log}(\varrho,\pi)\} + Ce^{-bt}W_{\log}(\varrho,\pi).$$

**Proof:** (a) Let $\{P_t^0 : t \geq 0\}$ be the transition kernel with admissible parameters $(\beta,b,\sigma,m,\nu = 0)$, and let $\{P_t^1 : t \geq 0\}$ be the transition kernel with admissible parameters $(\beta = 0, b, \sigma, m, \nu)$. In particular,

$$\int_{\mathbb{R}_{\geq 0}} e^{-\lambda z} P_t^1(0, dz) = \exp \left( - \int_0^t \int_0^\infty \left( 1 - e^{-\nu_s(\lambda)z} \right) \nu(dz) ds \right), \quad \lambda \geq 0,$$

where $v_t$ is obtained from (4.5). For all $\lambda \geq 0$,

$$\int_{\mathbb{R}_{\geq 0}} e^{-\lambda z} P_t(x, dz) = \int_{\mathbb{R}_{\geq 0}} e^{-\lambda z} P_t^0(x, dz) \int_{\mathbb{R}_{\geq 0}} e^{-\lambda z} P_t^1(0, dz),$$

yielding that $P_t(x,\cdot) = P_t^0(x,\cdot) * P_t^1(0,\cdot)$ holds for all $t, x \geq 0$. Combining the latter with Example 2.1 (a) and Lemma 2.4, we deduce

$$\|P_t(x,\cdot) - P_t(x,\cdot)\|_{TV} \leq \|P_t^0(x,\cdot) - P_t^0(x,\cdot)\|_{TV} \leq C \min \left\{1, e^{-bt}|x-y|\right\},$$

where the last inequality follows from Li and Ma (2015, Theorem 2.4) and the proof of Li and Ma (2015, Theorem 2.5).

(b) From Friesen et al. (2020b, Theorem 1.5) we know that the invariant measure satisfies $\pi \in \mathcal{P}_{\log}(\mathbb{R}_{\geq 0})$. Hence for each $\varrho \in \mathcal{P}_{\log}(\mathbb{R}_{\geq 0})$ one finds that $W_{\log}(\varrho,\pi)$ is finite. Let $H \in \mathcal{H}(\varrho,\pi)$ be the optimal coupling of $(\varrho,\pi)$ such that

$$W_{\log}(\varrho,\pi) = \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} \log (1 + |x-y|) H(dx,dy).$$

(4.7)

Here and below we let $C > 0$ be a generic constant. Using the invariance of $\pi$ combined with the convexity of the Wasserstein distance (see Lemma 2.3) shows that

$$\|P_t^* \varrho - \pi\|_{TV} \leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} \|P_t(x,\cdot) - P_t(y,\cdot)\|_{TV} H(dx,dy)$$

$$\leq C \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} \log \left(1 + e^{-bt}|x-y|\right) H(dx,dy),$$
where the last inequality following from statement (a) and $1 \wedge a \leq \log(2)^{-1} \log(1 + a)$ for $a \geq 0$. Using again (3.7) gives

$$
\|P_t^x \varrho - \pi\|_{TV} \leq C \min \left\{ e^{-b t}, \int_{R_0 \times R_0} \log (1 + |x - y|) H (dx, dy) \right\} \\
+ Ce^{-b t} \int_{R_0 \times R_0} \log (1 + |x - y|) H (dx, dy) \\
= C \min \left\{ e^{-b t}, W_{\log}(\varrho, \pi) \right\} + Ce^{-b t} W_{\log}(\varrho, \pi),
$$

where the last equality follows from (4.7).

Assertion (a) can also be derived from the method in Li and Ma (2015, Theorem 2.5) without the use of a convolution argument. However, assertion (b) can not be obtained by the method of Li and Ma (2015), since it relies on the fact that $\int_{R_0} \log(1 + z) \pi(dz) < \infty$, which was first shown in Friesen et al. (2020b, Theorem 1.5).

4.3. $Q$-process of a CBI process conditioned to be never extinct. In this section we consider a CBI process with branching mechanism

$$
\phi(\lambda) = b \lambda + \frac{1}{2} \sigma^2 \lambda^2 + \int_0^\infty \left( e^{-\lambda z} - 1 + \lambda z \right) m(dz),
$$

and immigration mechanism $\psi(\lambda) = 0$. Here $b \in R$, $\sigma \geq 0$, and $m$ is a Borel measure on $R_0$ satisfying $m(\{0\}) = 0$ and (4.1), i.e., $\int_0^\infty z \wedge z^2 m(dz) < \infty$. Thus, the admissible parameters are given by $(\beta = 0, b, \sigma, m, \nu = 0)$. In the literature such a process is called a CB process. Note that it has no immigration component. Applying our previous results to this particular case shows that this process has a unique invariant distribution whenever $b > 0$. Moreover, exponential ergodicity holds in the Wasserstein-1 distance. Assuming additionally Grey’s condition, one also obtains convergence in the total variation distance. However, the absence of immigration implies that 0 is a trap for the process and hence its invariant distribution is given by $\delta_0$, i.e., the population gets extinct.

As a next step one may study the long-time behavior of the process when conditioned on non-extinction. Let $(X^x_t)_{t \geq 0}$ be the corresponding CB process starting at $x \geq 0$ and define its extinction time by

$$
T_x = \inf \{ s \geq 0 : X^x_s = 0 \}.
$$

Note that $X^0_t = 0$ for all $t \geq 0$, so that we may assume that $x > 0$. Following Lambert (2007, Theorem 4.1) it was shown that under $\phi'(0) = b > 0$ the conditional laws satisfy

$$
\mathbb{P}(\cdot \mid T_x > s) = \mathbb{P}^\lambda(\Theta), \quad \Theta \in \mathcal{F}_t, \quad t \geq 0.
$$

It was also shown that $\mathbb{P}^\lambda$ uniquely determines a CBI process $(Z^x_t)_{t \geq 0}$ with branching mechanism $\phi$ as above, and immigration mechanism

$$
\psi(\lambda) = \phi'(\lambda) - \phi'(0).
$$

Since $\phi'(0) = b$, we find that

$$
\psi(\lambda) = \sigma^2 \lambda + \int_0^\infty \left( 1 - e^{-\lambda z} \right) zm(dz)
$$

and hence its admissible parameters are given by $(\beta, b, \sigma, m, \nu)$ with $\beta = \sigma^2$ and $\nu(dz) = zm(dz)$. The process $(Z^x_t)_{t \geq 0}$ is called $Q$-process.

It follows from Lambert (2007, Theorem 4.2) that this process converges a.s. to $+\infty$ when $b = 0$ or $b > 0$ but $\int_1^\infty z \log(z) m(dz) = +\infty$. Finally, if $b > 0$ and $\int_1^\infty z \log(z) m(dz) < \infty$, then the $Q$-process $(Z^x_t)_{t \geq 0}$ converges in distribution as $t \to \infty$ towards a limit distribution $\pi$. It can be shown that $\pi$ is a size-biased Yaglom distribution associated with the CB process $(X^x_t)_{t \geq 0}$. Note
that the condition \( \int_{0}^{1} z \log(z) m(dz) < \infty \) is simply \( \int_{1}^{\infty} \log(z) \nu(dz) < \infty \), so that the convergence in law is actually a particular case of the general convergence results discussed in previous section. Below we strengthen Lambert (2007, Theorem 4.2 (ii).b) towards convergence in Wasserstein and total variation distance.

**Theorem 4.5.** Let \( b > 0 \), \( \sigma \geq 0 \), and \( m \) be a Borel measure on \( \mathbb{R}_{\geq 0} \) satisfying \( m(\{0\}) = 0 \) and

\[
\int_{0}^{1} z^2 m(dz) < \infty, \quad \int_{1}^{\infty} z \log(z) m(dz) < \infty.
\]

Let \((Z_t^x)_{t \geq 0}\) be the corresponding \( Q \)-process and let \( \pi \) be its limit distribution. Finally, let \( p_t \) denote its transition probabilities. Then there exists a constant \( C > 0 \) such that

\[
W_{log}(p_t(x, \cdot), \pi) \leq Ce^{-bt} \left( 1 + \log(1 + x) + \int_{0}^{\infty} \log(1 + z) \pi(dz) \right), \quad \forall x, t > 0,
\]

where the right-hand side is finite. If \( m \) satisfies the stronger integrability condition

\[
\int_{1}^{\infty} z^{1+\lambda} m(dz) < \infty
\]

for some \( \lambda \in (0, 1) \), then we even have

\[
W_{\lambda}(p_t(x, \cdot), \pi) \leq e^{-b\lambda t} \left( x^\lambda + \int_{0}^{\infty} z^\lambda \pi(dz) \right) < \infty. \tag{4.8}
\]

Finally, if Grey’s condition (4.a) is satisfied, then

\[
\|p_t(x, \cdot) - \pi\|_{TV} \leq Ce^{-bt} \left( 1 + \log(1 + x) + \int_{0}^{\infty} \log(1 + z) \pi(dz) \right).
\]

**Proof:** First note that \((Z_t^x)_{t \geq 0}\) is a CBI process with admissible parameters \((\beta, b, \sigma, m, \nu)\) with \( \beta = \sigma^2 \) and \( \nu(dz) = zm(dz) \). Assume first that \( \int_{1}^{\infty} z^2 m(dz) < \infty \) which implies that the process has finite first moment. Hence it satisfies all assumptions of Theorem 3.5 which yields estimate (4.8) for \( \lambda = 1 \). Moreover, the proof thereof shows that

\[
W_1(p_t(x, \cdot), p_t(y, \cdot)) \leq e^{-bt}|x - y|, \quad x, y \geq 0, \quad t \geq 0. \tag{4.9}
\]

Assuming now that \( m \) satisfies the weaker condition \( \int_{1}^{\infty} z^{1+\lambda} m(dz) < \infty \) for some \( \lambda \in (0, 1) \), we may use a similar convolution trick to the proof of Theorem 4.4, i.e., write \( p_t(x, \cdot) = p_t^0(x, \cdot) * p_t(0, \cdot) \), where \( p_t^0 \) denote the transition probabilities of a CBI process with admissible parameters \((\beta = 0, b, \sigma, m, \nu) = 0\). Then using (4.9) for \( p_t^0 \) yields

\[
W_{\lambda}(p_t(x, \cdot), p_t(y, \cdot)) \leq W_{\lambda}(p_t^0(x, \cdot), p_t^0(y, \cdot)) \leq (W_1(p_t^0(x, \cdot), p_t^0(y, \cdot)))^\lambda \leq e^{-b\lambda t}|x - y|^\lambda.
\]

From this and the inequality \( W_{\lambda}(\delta_x, \pi) \leq \int_{\mathbb{R}_{\geq 0}} |x - z|^\lambda \pi(dz) \leq x^\lambda + \int_{\mathbb{R}_{\geq 0}} z \pi(dz) \) we readily deduce (4.8). Let us now assume that \( m \) satisfies \( \int_{1}^{\infty} z \log(1 + z) m(dz) < \infty \). Using again the convexity of the Wasserstein distance and the same decomposition \( p_t(x, \cdot) = p_t^0(x, \cdot) * p_t(0, \cdot) \), we find that

\[
W_{log}(p_t(x, \cdot), p_t(y, \cdot)) \leq \log(1 + W_1(p_t^0(x, \cdot), p_t^0(y, \cdot))) \leq \log(1 + e^{-bt}|x - y|).
\]
The assertion now follows by similar arguments to the proof of Theorem 4.4 with the Wasserstein distance instead of the TV distance, i.e.,

\[ W_{\log}(p_t(x, \cdot), \pi) \leq C \min\{e^{-bt}, W_{\log}(\delta_x, \pi)\} + Ce^{-bt}W_{\log}(\delta_x, \pi) \]

\[ \leq Ce^{-bt}\left(1 + \log(1 + x) + \int_{\mathbb{R}_{\geq 0}} \log(1 + z)\pi(dz)\right), \]

where the last inequality follows from \( W_{\log}(\delta_x, \pi) \leq \int_{\mathbb{R}_{\geq 0}} \log(1 + |x - z|)\pi(dz) \leq \log(1 + x) + \int_{\mathbb{R}_{\geq 0}} \log(1 + z)\pi(dz). \) Finally, convergence in the TV distance is a particular case of Theorem 4.4 combined with \( W_{\log}(\delta_x, \pi) \leq \log(1 + x) + \int_{\mathbb{R}_{\geq 0}} \log(1 + z)\pi(dz). \)

\[ \square \]

4.4. Continuous-state branching processes with immigration in Lévy random environments. Following He et al. (2018) and Palau and Pardo (2017, 2018), below we introduce a continuous-state branching process with immigration in a Lévy random environment (CBIRE process). Namely, let \( \beta, b_E \in \mathbb{R}, b \geq 0, \sigma, \sigma_E \geq 0, \) and \( m, \nu, \mu_E \) be Lévy measures on \( \mathbb{R} \) such that

\[ m((-\infty, 0]) = 0, \quad \nu((-\infty, 0]) = 0, \quad \int_{\mathbb{R}_{\geq 0}} 1 \wedge z\nu(dz) < \infty. \]

Let \( (\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P}) \) be a stochastic basis satisfying the usual conditions rich enough to support

- an \( (\mathcal{F}_t)_{t \geq 0} \)-Gaussian white noise \( W(dt, du) \) with intensity \( dtdu; \)
- an \( (\mathcal{F}_t)_{t \geq 0} \)-Poisson random measure \( N_0(dt, dz, du) \) on \( \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \) with intensity \( dtm(dz)du; \)
- an \( (\mathcal{F}_t)_{t \geq 0} \)-Poisson random measure \( N_1(dt, dz) \) on \( \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \) with intensity \( dt\nu(dz); \)
- an \( (\mathcal{F}_t)_{t \geq 0} \)-Brownian motion \( \{B_t : t \geq 0\}; \)
- an \( (\mathcal{F}_t)_{t \geq 0} \)-Poisson random measure \( M(dt, dz) \) on \( \mathbb{R}_{\geq 0} \times \mathbb{R} \) with intensity \( dt\mu_E(dz). \)

Suppose that these random objects are mutually independent. Define an \( (\mathcal{F}_t)_{t \geq 0} \)-Lévy process \( \{Z_t : t \geq 0\} \) by

\[ Z_t = b_E t + \sigma_E B_t + \int_0^t \int_{[-1,1]} (e^z - 1)\tilde{M}(ds, dz) + \int_0^t \int_{[-1,1]c} (e^z - 1)M(ds, dz), \quad (4.10) \]

where \([-1,1]c = \mathbb{R}\setminus[-1,1], \tilde{M}(ds, dz) := M(ds, dz) - ds\mu_E(dz).\) Note that \( \{Z_t : t \geq 0\} \) has no jump less than \(-1.\) Then it was shown in He et al. (2018, Theorem 5.1) and Palau and Pardo (2018, Theorem 1) that

\[ X_t = X_0 + \int_0^t (\beta - bX_s) ds + \sigma \int_0^t \int_0^\infty 1_{\{u \leq X_s\}} W(ds, du) \]

\[ + \int_0^t \int_0^\infty z1_{\{u \leq X_{s-}\}} N_0(ds, dz, du) + \int_0^t \int_0^\infty zN_1(ds, dz) + \int_0^t X_{s-}dZ_s, \quad (4.11) \]

has for each \( \mathcal{F}_0 \)-measurable random variable \( X_0 \geq 0 \) a pathwise unique nonnegative strong solution \( \{X_t : t \geq 0\}. \) We call the corresponding Markov process CBIRE process.

In view of He et al. (2018, Theorem 5.4), the Markov process \( \{X_t : t \geq 0\} \) has Feller transition semigroup \( \{P_t : t \geq 0\} \) and its transition kernels \( P_t(x, dy) \) satisfy

\[ \int_{\mathbb{R}_{\geq 0}} e^{-\lambda y} P_t(x, dy) = \mathbb{E} \left[ \exp \left( -x\psi_{0,t}(\lambda) - \int_0^t \psi \left( v_{s,t}(\lambda) \right) ds \right) \right], \quad (4.12) \]
Here $\phi$ and $\psi$ are the corresponding branching and immigration mechanisms for the CBI process with admissible parameters $(\beta, b, \sigma, m, \nu)$ and $r \mapsto v_{r,t}^\xi(\lambda)$ is the pathwise unique nonnegative solution to

$$v_{r,t}^\xi(\lambda) = e^{\xi(t) - \xi(r)}\lambda - \int_r^t e^{\xi(s) - \xi(r)}\phi\left(v_{s,t}^\xi(\lambda)\right)\,ds, \quad 0 \leq r \leq t,$$

where $\{\xi_t : t \geq 0\}$ is an $(\mathcal{F}_t)_{t \geq 0}$-Lévy process defined by

$$\xi_t = a_Et + \sigma_E B_t + \int_0^t \int_{[-1,1]} z\tilde{M}(ds, dz) + \int_0^t \int_{[-1,1]} zM(ds, dz),$$

with the drift coefficients $b_E$ and $a_E$ being related by

$$b_E = a_E + \frac{\sigma_E^2}{2} + \int_{[-1,1]} (e^z - 1 - z)\mu_E(dz).$$

The next remark provides an alternative representation for (4.11) on which our results are based.

**Remark 4.6.** In view of (4.10), equation (4.11) is equivalent to

$$X_t = X_0 + \int_0^t (\beta + (b_E - b)X_s)\,ds + \int_0^t \int_0^\infty zN_1(ds, dz) + \int_0^t \int_{[-1,1]} X_{s-}(e^z - 1)M(ds, dz)$$

$$+ \sigma \int_0^t \int_0^\infty 1_{\{u \leq X_s\}} W(ds, du) + \sigma_E \int_0^t X_s dB_s$$

$$+ \int_0^t \int_0^\infty z1_{\{u \leq X_s\}} \tilde{N}_0(ds, dz, du) + \int_0^t \int_{[-1,1]} X_{s-}(e^z - 1)\tilde{M}(ds, dz).$$

So far, the comparison principle has not been obtained for the CBIRE process. Below we show that (4.11) is a special case of (1.1) which satisfies the conditions of Theorem 3.3 and hence also satisfies the comparison principle.

**Proposition 4.7.** Assume that

$$\int_{(1,\infty)} vz(dz) + \int_{(1,\infty)} zm(dz) + \int_{(1,\infty)} e^z\mu_E(dz) < \infty. \quad (4.13)$$

Then (4.11) has the comparison property.

**Proof:** Let us first show that (4.11) is a particular case of (1.1). The drift coefficient is simply given by $b(x) = b_1(x) - b_2(x)$ with $b_1(x) = \beta - (b - b_E)x$ and $b_2(x) = 0$ for $x \in \mathbb{R}_{\geq 0}$. For the diffusion component set $E = \{1, 2\} \times \mathbb{R}_{\geq 0}$ and $\nu(dk, du) = \delta_1(dk)du + \delta_2(dk)\delta_0(du)$ on $E$. Then $W(ds, dk, du) := \delta_1(dk)W(ds, du) + dB_s\delta_2(dk)\delta_0(du)$ defines an $(\mathcal{F}_t)_{t \geq 0}$-Gaussian white noise on $\mathbb{R}_{\geq 0} \times E$ with intensity measure $dsk\nu(dk, du)$. Let $\sigma(x, k, u) := \sigma_11_{\{k=1\}}1_{\{u \leq x\}} + \sigma_E1_{\{k=2\}}1_{\{0\}}(u)x$ for $(x, k, u) \in \mathbb{R}_{\geq 0} \times E$. We see that

$$\int_0^t \int_E \sigma(X_s, k, u) W(ds, dk, du) = \sigma \int_0^t \int_{\mathbb{R}_{\geq 0}} 1_{\{u \leq X_s\}} W(ds, du) + \sigma_E \int_0^t X_s dB_s.$$
For condition (3.d) we observe that for $(x, k, z, u) \in \mathbb{R}_{\geq 0} \times U_0$ yields
\[
\int_0^t \int_{U_0} g_0(X_{s-}, k, z, u) \tilde{N}_0(ds, dk, dz, du) = \int_0^t \int_0^\infty \int_0^\infty z \mathbb{1}_{\{u \leq X_{s-}\}} \tilde{N}_0(ds, dz, du)
+ \int_0^t \int_{-1}^1 (e^z - 1) X_{s-} \tilde{M}(ds, dz)
\]

Finally, let $U_1 = \{1, 2\} \times \mathbb{R}$ and define $\mu_1(dk, dz) = \mathbb{1}_{\mathbb{R}_{\geq 0}}(z) \delta_1(dk) \nu(dz) + \delta_2(dk) \mu_E(dz)$ on $U_1$. Then $N_1(ds, dk, dz) = \delta_1(dk) N_1(ds, dz) + \delta_2(dk) M(ds, dz)$ defines an $(\mathcal{F}_t)_{t \geq 0}$-Poisson random measure on $\mathbb{R}_{\geq 0} \times U_1$ with intensity $d\mu_1(dk, dz)$. Letting $g_1(x, k, z) = \mathbb{1}_{\{k=1\}} \mathbb{1}_{\mathbb{R}_{\geq 0}}(z) z + \mathbb{1}_{\{k=2\}} \mathbb{1}_{[-1,1]}(z)(\exp(z) - 1) x$ for $(x, k, z) \in \mathbb{R}_{\geq 0} \times U_1$ yields
\[
\int_0^t \int_{U_1} g_1(X_{s-}, k, z) N_1(ds, dk, dz) = \int_0^t \int_0^\infty z N_1(ds, dz) + \int_0^t \int_{[-1,1]} (e^z - 1) X_{s-} M(ds, dz).
\]

This shows that (4.11) is indeed a particular case of (1.1).

Next we verify conditions (3.a) – (3.e) and show that $(m)_1$ holds. Writing $(k, z) = u$, condition (3.a) follows from
\[
\sup_{y \in [0, x]} |g_1(y, u)| \leq \mathbb{1}_{\{k=1\}} \mathbb{1}_{\mathbb{R}_{\geq 0}}(z) z + \mathbb{1}_{\{k=2\}} \mathbb{1}_{[-1,1]}(z)(\exp(z) - 1) x =: \overline{g_1}(x, u)
\]
and
\[
b(x) + \int_{U_1} |\overline{g_1}(x, u)| \mu_1(du) = \beta - (b - b_E)x + \int_{\mathbb{R}_{\geq 0}} z \nu(dz) + \int_{[-1,1]} |\exp(z) - 1| x \mu_E(dz)
\leq \left( \beta + \int_{\mathbb{R}_{\geq 0}} z \nu(dz) \right) + x \left( b + |b_E| + \int_{[-1,1]} |\exp(z) - 1| \mu_E(dz) \right),
\]
where both integrals are finite due to (4.13). Condition (3.b) follows directly from
\[
|b_1(x) - b_1(y)| + \int_{U_1} |g_1(x, u) - g_1(y, u)| \mu_1(du)
\leq |b - b_E| |x - y| + |x - y| \int_{[-1,1]} |\exp(z) - 1| \mu_E(dz) =: r_1(|x - y|).
\]

Condition (3.c) follows from
\[
\int_E \sigma(x, u)^2 \kappa(du) = \sigma^2 \int_{\mathbb{R}_{\geq 0}} \mathbb{1}_{\{u \leq x\}} du + \sigma_E^2 x^2 \leq (\sigma^2 + \sigma_E^2)(2 + x)^2
\]
and for $j \geq 1$ with $0 \leq x, y \leq j$
\[
\int_E |\sigma(x, u) - \sigma(y, u)|^2 \kappa(du) \leq \sigma^2 \int_{\mathbb{R}_{\geq 0}} |\mathbb{1}_{\{u \leq x\}} - \mathbb{1}_{\{u \leq y\}}| du + \sigma_E^2 |x - y|^2
\leq (\sigma^2 + 2j \sigma_E^2) |x - y|.
\]

For condition (3.d) we observe that for $0 \leq y \leq x$,
\[
|g_0(y, k, z, u)| \leq \mathbb{1}_{\{k=1\}} \mathbb{1}_{\{u \leq x\}} \mathbb{1}_{\mathbb{R}_{\geq 0}}(z) z + \mathbb{1}_{\{k=2\}} \mathbb{1}_{[-1,1]}(z)(\exp(z) - 1) x =: \overline{g_0}(x, k, z, u).
\]
One has
\[ \int_{U_0} (g_0(x, u) \wedge g_0(x, u)^2) \mu_0(du) = \int_{\mathbb{R}^2_0} 1_{\{u \leq x\}} (z \wedge z^2) m(dz)du + \int_{[-1,1]} \min\{|\exp(z) - 1|, |\exp(z) - 1|^2\} \mu_E(dz) \leq (2 + x)^2 \left( \int_{\mathbb{R}_0} z \wedge z^2 m(dz) + \int_{[-1,1]} |\exp(z) - 1|^2 \mu_E(dz) \right). \]

Moreover, it holds that
\[ \int_{U_0} 1_{\{|g_0(x, u)| \leq 1\}} |g_0(x, u)|^2 \mu_0(du) \leq x \int_{[0,1]} z^2 m(dz) + x^2 \int_{[-1,1]} |\exp(z) - 1|^2 \mu_E(dz) \leq \left( \int_{[0,1]} z^2 m(dz) + \int_{[-1,1]} |\exp(z) - 1|^2 \mu_E(dz) \right) (2 + x^2) \]

and for each \( j \geq 1 \) with \( 0 \leq x, y \leq j \)
\[ \int_{U_0} (|g_0(x, u) - g_0(y, u)| \wedge |g_0(x, u) - g_0(y, u)|^2) \mu_0(du) \leq |x - y| \int_{\mathbb{R}_0} (z \wedge z^2) m(dz) + \int_{[-1,1]} [(|x - y| |\exp(z) - 1|) \wedge (|x - y|^2 |\exp(z) - 1|^2)] \mu_E(dz) \leq |x - y| \int_{\mathbb{R}_0} (z \wedge z^2) m(dz) + (1 + 2j)|x - y| \int_{[-1,1]} |\exp(z) - 1|^2 \mu_E(dz). \]

This proves (3.d). Condition (3.e) follows from
\[ x + g_0(x, k, z, u) = 1_{\{k = 1\}} 1_{\{u \leq x\}} 1_{\mathbb{R}_0} (z) + 1_{\{k = 2\}} 1_{[-1,1]} (\exp(z) - 1) x + x \]
\[ = 1_{\{k = 1\}} 1_{\{u \leq x\}} 1_{\mathbb{R}_0} (z) + 1_{\{k = 2\}} 1_{[-1,1]} (\exp(z) x + (1 - 1_{\{k = 2\}} 1_{[-1,1]} \exp(z)) x \]
and likewise
\[ x + g_1(x, k, z) = 1_{\{k = 1\}} 1_{\mathbb{R}_0} (z) + 1_{\{k = 2\}} 1_{[-1,1]} (\exp(z) x + (1 - 1_{\{k = 2\}} 1_{[-1,1]} \exp(z)) x. \]

Finally, the moment condition \( (m)_1 \) follows from
\[ \int_{U_1} 1_{\{|g_1(x, u)| > 1\}} |g_1(x, u)| \mu_1(du) \leq \int_{\mathbb{R}_0} z \nu(dz) + x \int_{[-1,1]} |\exp(z) - 1| \mu_E(dz) \]
and
\[ \int_{U_0} 1_{\{|g_0(x, u)| > 1\}} |g_0(x, u)| \mu_0(du) \leq x \int_{\{z > 1\}} z m(dz) + \int_{[-1,1]} 1_{\{|\exp(z) - 1| > 1\}} x |\exp(z) - 1| \mu_E(dz) \leq x \int_{\{z > 1\}} z m(dz) + x \int_{[-1,1]} |\exp(z) - 1| \mu_E(dz). \]

Existence of limiting distributions (and hence invariant measures) was recently characterized in He et al. (2018). In the following we present sufficient conditions for both the ergodicity in the
Theorem 4.9. Let \( \{P_t : t \geq 0\} \) be the transition semigroup with transition kernels defined by (4.12) and denote by \( \{P_t^* : t \geq 0\} \) the dual semigroup. Suppose that (4.13) holds and that
\[
b > E[Z_1].
\]
Then, for all \( \varrho, \bar{\varrho} \in \mathcal{P}_1(\mathbb{R}_{\geq 0}) \), we have
\[
W_1(P_t^* \varrho, P_t^* \bar{\varrho}) \leq e^{-(b-E[Z_1])t}W_1(\varrho, \bar{\varrho}), \quad t \geq 0.
\]
In particular, there exists a unique invariant distribution \( \pi \in \mathcal{P}(\mathbb{R}_{\geq 0}) \). Moreover, \( \pi \) belongs to \( \mathcal{P}_1(\mathbb{R}_{\geq 0}) \) and, for all \( \varrho \in \mathcal{P}_1(\mathbb{R}_{\geq 0}) \),
\[
W_1(P_t^* \varrho, \pi) \leq e^{-(b-E[Z_1])t}W_1(\varrho, \pi), \quad t \geq 0.
\]

Proof: It remains to verify condition (3.f). First observe that
\[
\tilde{b}(x) := b(x) + \int_{U_1} g_1(x,u)\mu_1(\text{d}u)
= \beta + \int_{\mathbb{R}_{\geq 0}} z\nu(\text{d}z) + \left( \int_{[-1,1]^c} (\exp(z) - 1)\mu_E(\text{d}z) - (b - b_E) \right) x
\]
and hence for \( 0 \leq x \leq y \)
\[
\tilde{b}(y) - \tilde{b}(x) = -\left( b - b_E - \int_{[-1,1]^c} (\exp(z) - 1)\mu_E(\text{d}z) \right) (y - x).
\]
Using \( E[Z_1] = b_E + \int_{[-1,1]^c}(\exp(z) - 1)\mu_E(\text{d}z) \) we conclude condition (3.f) from (4.14). \( \Box \)

Theorem 4.9. Let \( \{P_t : t \geq 0\} \) be the transition semigroup with transition kernels defined by (4.12) and denote by \( \{P_t^* : t \geq 0\} \) the dual semigroup. Suppose that (4.14) and Grey’s condition (4,a) is satisfied. Let \( \pi \) be the unique invariant distribution. Then, for any \( \varrho \in \mathcal{P}_1(\mathbb{R}_{\geq 0}) \),
\[
\|P_t^* \varrho - \pi\|_{TV} \leq 2E \left[ \pi_{0,t}^\xi \right] W_1(\varrho, \pi), \quad t \geq 0,
\]
where \( \pi_{0,t}^\xi := \lim_{\lambda \to \infty} \xi_{0,t}(\lambda) \in [0, \infty) \). If, in addition, \( \liminf_{t \to \infty} \xi(t) = -\infty \) almost surely, then
\[
\lim_{t \to \infty} \|P_t^* \varrho - \pi\|_{TV} = 0.
\]

Proof: As a consequence of Grey’s condition, He et al. (2018, Theorem 4.1) applies, yielding that \( \pi_{0,t}^\xi \in [0, \infty) \) almost surely for all \( t > 0 \). Let \( f \in B_b(\mathbb{R}_{\geq 0}) \) be arbitrary. Arguing as in the proof of He et al. (2018, Theorem 4.5), we observe that, for \( 0 \leq x \leq y \),
\[
|P_t f(x) - P_t f(y)| \leq 2E \left[ 1 - e^{-(y-x)\pi_{0,t}^\xi} \right] \leq 2E \left\{ 1, |x - y| \pi_{0,t}^\xi \right\}.
\]
Taking the supremum over all \( f \in B_b(\mathbb{R}_{\geq 0}) \) with \( \|f\|_{\infty} \leq 1 \) shows that \( \|P_t(x,\cdot) - P_t(y,\cdot)\|_{TV} \leq 2E\min\{1,|x - y|\pi_{0,t}^\xi\} \). Let now \( \varrho \in \mathcal{P}_1(\mathbb{R}_{\geq 0}) \) and let \( H \) be any coupling of \((\varrho,\cdot)\). By convexity of the Wasserstein distance, we obtain
\[
\|P_t^* \varrho - \pi\|_{TV} \leq \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} \|P_t(x,\cdot) - P_t(y,\cdot)\|_{TV} H(\text{d}x,\text{d}y)
\]
\[
\leq 2 \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} E \left\{ \min\left\{ 1, |x - y| \pi_{0,t}^\xi \right\} \right\} H(\text{d}x,\text{d}y).
\]
If \( \liminf_{t \to \infty} \xi(t) = -\infty \), then \( \lim_{t \to \infty} \overline{\eta}_{0,t}^\xi = 0 \) in view of He et al. (2018, Corollary 4.4) and, thus, (4.16) follows from dominated convergence. Finally, we conclude the estimate (4.15) by estimating
\[
\int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} \mathbb{E} \left[ \min \left\{ 1, |x - y| \overline{\eta}_{0,t}^\xi \right\} \right] H(dx, dy) \leq \mathbb{E} \left[ \overline{\eta}_{0,t}^\xi \right] \int_{\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}} |x - y| H(dx, dy),
\]
where we choose \( H \) as the optimal coupling of \((\rho, \pi)\) with respect to \( W_1 \).

The decay rate for \( \overline{\eta}_{0,t}^\xi \) as \( t \to \infty \) was studied by Palau and Pardo (2017) for a continuous-state branching process in Brownian random environment with stable branching. For the same class of processes but in a general Lévy environment this problem was studied by Li and Xu (2018).

Acknowledgements

We are very grateful to the anonymous referee, whose valuable comments have led to an improvement of this manuscript.

Appendix

Lemma A.1. Let \( \lambda > 0 \) and set \( V_\lambda(x) = (2 + x)^{\lambda} \). Then the following assertions hold.

(a) There exists a constant \( C_\lambda > 0 \) such that for \( z \in \mathbb{R} \) and \( x \geq 0 \) with \( x + z \geq 0 \) it holds that
\[
|V_\lambda(x + z) - V_\lambda(x)| \leq C_\lambda (2 + x)^{\lambda - 1} 1_{\{|z| \leq 1\}} |z| + C_\lambda \left( 1_{(0,1]}(\lambda) + 1_{(1,\infty)}(\lambda)(2 + x)^{\lambda - 1} \right) 1_{\{|z| > 1\}} |z|^\lambda.
\]

(b) There exists another constant \( \tilde{C}_\lambda > 0 \) such that for \( z \in \mathbb{R} \) and \( x \geq 0 \) with \( x + z \geq 0 \) it holds that
\[
|V_\lambda(x + z) - V_\lambda(x) - zV'_\lambda(x)| \leq \tilde{C}_\lambda (2 + x)^{\lambda - 2} 1_{\{|z| \leq 1\}} |z|^2 + \tilde{C}_\lambda \left( 1_{(0,1]}(\lambda) + 1_{(1,2]}(\lambda)(2 + x)^{\lambda - 1} + 1_{(2,\infty)}(\lambda)(2 + x)^{\lambda - 2} \right) 1_{\{|z| > 1\}} |z|^{\max\{1,\lambda\}}.
\]

Proof: (a) Using the mean-value theorem we find some \( \xi \) lying between \( 0 \) and \( z \) such that
\[
V_\lambda(x + z) - V_\lambda(x) = \lambda z (2 + x + \xi)^{\lambda - 1}.
\]
Consider first the case where \( \lambda > 1 \). For \( |z| \leq 1 \) we use \(|(2 + x + \xi)^{\lambda - 1}| \leq (2 + x + |z|)^{\lambda - 1} \leq (3 + x)^{\lambda - 1} \leq 2^{\lambda - 1}(2 + x)^{\lambda - 1}\) to find that
\[
|V_\lambda(x + z) - V_\lambda(x)| \leq \lambda 2^{\lambda - 1}(2 + x)^{\lambda - 1} |z|.
\]
For \( |z| > 1 \) we use the inequality \( 2 + a + b \leq (2 + a)(2 + b) \) for \( a, b \geq 0 \) to find that
\[
|V_\lambda(x + z) - V_\lambda(x)| = \lambda |z|(2 + x + \xi)^{\lambda - 1}
\leq \lambda |z|(2 + x + |z|)^{\lambda - 1}
\leq \lambda |z| (2 + x)^{\lambda - 1} (2 + |z|)^{\lambda - 1}
\leq 3^{\lambda - 1} \lambda (2 + x)^{\lambda - 1} |z|^\lambda.
\]
This proves the assertion for \( \lambda > 1 \). Now assume that \( \lambda \in (0,1) \). If \( |z| \leq 1 \), then \( 2 + \xi \geq 2 - |z| \geq 1 \) and hence \( 2 + x + \xi \geq 1 + x \). This yields
\[
|V_\lambda(x + z) - V_\lambda(x)| = \lambda |z|(2 + x + \xi)^{\lambda - 1}
\leq \lambda (1 + x)^{\lambda - 1} |z|
= 2^{1 - \lambda} \lambda (2 + 2x)^{\lambda - 1} |z|
\leq 2^{1 - \lambda} \lambda (2 + x)^{\lambda - 1} |z|.
\]
Finally, if $|z| > 1$, then we find that
\[
|V_\lambda(x + z) - V_\lambda(x)| = \left| (2 + x + z)^\lambda - (2 + x)^\lambda \right|
\leq |(2 + x + z) - (2 + x)|^\lambda = |z|^\lambda.
\]

Combining all estimates proves the assertion.

(b) To prove the second inequality, we use the mean-value theorem twice to find that
\[
V_\lambda(x + z) - V_\lambda(x) - zV_\lambda'(x) = z^2 \int_0^1 \int_0^1 rV_\lambda''(x + rsz)drds
= z^2\lambda(\lambda - 1) \int_0^1 \int_0^1 r(2 + x + rsz)^{\lambda-2}drds,
\]
where the integrand is non-negative and well-defined since $2 + x + rsz \geq 2$ holds for all $z \in \mathbb{R}$ and $x \geq 0$ satisfying $x + z \geq 0$. Suppose first that $|z| \leq 1$. If $\lambda \in (0, 2]$, then we use that $2 + x + rsz \geq 2 + x - |z| \geq 1 + x$ to find that
\[
|V_\lambda(x + z) - V_\lambda(x) - zV_\lambda'(x)| \leq \lambda|\lambda - 1||z|^2(1 + x)^{\lambda-2}
\leq 2^{\lambda-1} \lambda|\lambda - 1||z|^2(2 + x)^{\lambda-2}.
\]

If $\lambda > 2$, then we use that $2 + x + rsz \leq 3 + x$ to find that
\[
|V_\lambda(x + z) - V_\lambda(x) - zV_\lambda'(x)| \leq \lambda(\lambda - 1)(3 + x)^{\lambda-2}|z|^2
\leq \lambda(\lambda - 1)2^{\lambda-2}(2 + x)^{\lambda-2}|z|^2.
\]

The last two estimates prove the assertion for the case $|z| \leq 1$. Now suppose that $|z| > 1$. For $\lambda \geq 2$ we find that
\[
(2 + x + rsz)^{\lambda-2} \leq (2 + x + |z|)^{\lambda-2} \leq (2 + x)^{\lambda-2}(2 + |z|)^{\lambda-2},
\]
which gives
\[
|V_\lambda(x + z) - V_\lambda(x) - zV_\lambda'(x)| \leq \lambda(\lambda - 1)(2 + x)^{\lambda-2}|z|^2(2 + |z|)^{\lambda-2}
\leq \lambda(\lambda - 1)3^{\lambda-2}(2 + x)^{\lambda-2}|z|^\lambda.
\]

Finally, if $\lambda \in (1, 2)$, then we use part (a) to find that
\[
|V_\lambda(x + z) - V_\lambda(x) - zV_\lambda'(x)| \leq |V_\lambda(x + z) - V_\lambda(x)| + |z|V_\lambda'(x)
\leq C_\lambda(2 + x)^{\lambda-1}|z|^\lambda + \lambda|z|(2 + x)^{\lambda-1}
\leq (C_\lambda + \lambda)(2 + x)^{\lambda-1}|z|^\lambda,
\]
while for $\lambda \in (0, 1]$ we obtain
\[
|V_\lambda(x + z) - V_\lambda(x) - zV_\lambda'(x)| \leq |V_\lambda(x + z) - V_\lambda(x)| + |z|V_\lambda'(x)
\leq C_\lambda|z|^\lambda + \lambda|z|(2 + x)^{\lambda-1}
\leq (C_\lambda + \lambda)|z|^{\max(1, \lambda)}.
\]

This completes the proof of part (b).

\[\square\]

\textbf{Lemma A.2.} For $x \geq 0$ set $V(x) = \log(2 + x)$. Then there exists a constant $C_{\log} > 0$ such that for $z \in \mathbb{R}$ and $x \geq 0$ with $x + z \geq 0$ it holds that
\[
|V(x + z) - V(x)| \leq \mathbbm{1}_{\{|z| \leq 1\}} \frac{|z|}{1 + x} + C_{\log} \mathbbm{1}_{\{|z| > 1\}} \frac{1 + \log(1 + |z|)}{2 + x}.
\]
and

\[ |V(x + z) - V(x) - zV'(x)| \leq 1_{\{|z|\leq 1\}} \frac{|z|^2}{(1 + x)^2} + C \log 1_{\{|z|>1\}} \frac{|z|}{2 + x}. \]

Proof: For the first inequality we first consider the case \(|z| \leq 1\). Using the mean-value theorem we find some \(\xi\) lying between \(0\) and \(z\) such that

\[ |V(x + z) - V(x)| = \left| \frac{z}{2 + x + \xi} \right| \leq \frac{|z|}{2 + x + \xi} \leq \frac{|z|}{1 + x}. \]

where we have used that \(2 + x + \xi \geq 1 + x\). For \(|z| > 1\) we use the monotonicity of the logarithm and then for \(a, d \geq 0\) the inequality \(\log(1 + a \cdot d) \leq C \min\{a, \log(1 + d)\} + Ca \log(1 + d)\), where \(C > 0\) is a constant (see Friesen et al. (2020b, Lemma A.5)), to find that

\[ |V(x + z) - V(x)| = \log \left( 1 + \frac{|z|}{2 + x} \right) \]

\[ \leq C \min \left\{ \frac{1}{2 + x}, \log(1 + |z|) \right\} + \frac{C}{2 + x} \log(1 + |z|) \]

\[ \leq \frac{C}{2 + x} + C \frac{\log(1 + |z|)}{2 + x}. \]

Combining both estimates proves the first inequality. For the second inequality we observe that

\[ V(x + z) - V(x) - zV'(x) = z^2 \int_0^1 \int_0^1 rV''(x + rsz)drds \]

\[ = -z^2 \int_0^1 \int_0^1 \frac{r}{(2 + x + rsz)^2}drds. \]

Since \(2 + x + rsz \geq 1 + x\) holds for \(|z| \leq 1\), we conclude that

\[ |V(x + z) - V(x) - zV'(x)| \leq \frac{|z|^2}{(1 + x)^2}. \]

Finally, if \(|z| > 1\) then we use the previously shown inequality to find that

\[ |V(x + z) - V(x) - zV'(x)| \leq |V(x + z) - V(x)| + |z| |V'(x)| \]

\[ \leq C \frac{1}{2 + x} + C \frac{1}{2 + x} \log(1 + |z|) + \frac{|z|}{2 + x} \]

\[ \leq \frac{C + (C + 1)|z|}{2 + x} \leq \frac{(2C + 1)|z|}{2 + x}. \]

This proves the second inequality. \(\square\)

**Lemma A.3.** Let \((b, \sigma, g_0, g_1)\) be admissible parameters and that conditions (3.a) – (3.e) are satisfied. Let \(\{X_t : t \geq 0\}\) be the unique strong \([0, \infty]-valued\) solution of (1.1). Then the following assertions hold:

(a) If condition \((m)_\lambda\) holds for some \(\lambda > 0\), then there exists a constant \(c(\lambda) > 0\) such that

\[ \mathbb{E} \left[ X_t^\lambda \right] \leq \mathbb{E} \left[ (2 + X_0)^\lambda \right] \exp \left( c(\lambda) t \right), \quad t \geq 0. \]

In particular, if \(\mathbb{E} \left[ (2 + X_0)^\lambda \right] < \infty\), then the unique solution of (1.1) is a.s. finite.

(b) If condition \((m)_{\log}\) holds, then there exists a constant \(c_{\log} > 0\) such that

\[ \mathbb{E} \left[ \log(2 + X_t) \right] \leq \mathbb{E} \left[ \log(2 + X_0) \right] + c_{\log} t, \quad t \geq 0. \]

In particular, if \(\mathbb{E} \left[ \log(2 + X_0) \right] < \infty\), then the unique solution of (1.1) is a.s. finite.
Proof: (a) Let \( V_\lambda(x) = (2 + x)^\lambda \) and set \( \tau_n = \inf\{t \geq 0 : X_t \geq n\} \). Then \( X_{t-} \leq n \) for \( 0 \leq t \leq \tau_n \). Applying the Itô formula to \( V_\lambda(X_t) \) and stopping by \( \tau_n \) yield

\[
V_\lambda(X_{t\wedge \tau_n}) = V_\lambda(X_0) + A_{t\wedge \tau_n} + M_{t\wedge \tau_n},
\]

where \((M_{t\wedge \tau_n})_{t \geq 0}\) is a local martingale and \((A_{t\wedge \tau_n})_{t \geq 0}\) is of finite variation given by

\[
M_{t\wedge \tau_n} = \int_0^{t\wedge \tau_n} \int_E \sigma(X_{s-}, u) V_\lambda'(X_{s-}) W(ds, du) + \int_0^{t\wedge \tau_n} \int_{U_0} (V_\lambda(X_{s-} + g_0(X_{s-}, u)) - V_\lambda(X_{s-})) \tilde{N}_0(ds, du),
\]

\[
A_{t\wedge \tau_n} = \int_0^{t\wedge \tau_n} b(X_{s-}) V_\lambda'(X_{s-}) ds + \frac{1}{2} \int_0^{t\wedge \tau_n} \int_E \sigma(X_{s-}, u)^2 V_\lambda''(X_{s-}) \sigma(ds, du) ds
\]

\[
+ \int_0^{t\wedge \tau_n} \int_{U_1} (V_\lambda(X_{s-} + g_1(X_{s-}, u)) - V_\lambda(X_{s-})) N_1(ds, du)
\]

\[
+ \int_0^{t\wedge \tau_n} \int_{U_0} (V_\lambda(X_{s-} + g_0(X_{s-}, u)) - V_\lambda(X_{s-}) - V_\lambda'(X_{s-}) g_0(X_{s-}, u)) \mu_0(du) ds.
\]

To estimate the local martingale part, we use the Burkholder-Davis-Gundy inequality, Lemma A.1, conditions (3.c) and (3.d), and \((m)_\lambda\), to find that

\[
\text{E} \left[ \sup_{t \in [0,T]} |M_{t\wedge \tau_n}| \right] \\
\leq \text{E} \left[ \left( \int_0^{T\wedge \tau_n} V_\lambda'(X_{s-})^2 \left( \int_E \sigma(X_{s-}, u)^2 \sigma(ds, du) \right) ds \right)^{1/2} \right]
\]

\[
+ \text{E} \left[ \left( \int_0^{T\wedge \tau_n} \int_{U_0} 1_{\{g_0(X_{s-}, u) \leq 1\}} \left( V_\lambda(X_{s-} + g_0(X_{s-}, u)) - V_\lambda(X_{s-}) \right)^2 \mu_0(du, ds) \right)^{1/2} \right]
\]

\[
+ 2\lambda \text{E} \left[ \left( \int_0^{T\wedge \tau_n} \int_{U_0} 1_{\{g_0(X_{s-}, u) > 1\}} \left| V_\lambda(X_{s-} + g_0(X_{s-}, u)) - V_\lambda(X_{s-}) \right| \mu_0(du) ds \right) \right]
\]

\[
\leq \lambda \text{E} \left[ \left( \int_0^{T\wedge \tau_n} (2 + X_{s-})^{2(\lambda-1)} \left( \int_E \sigma(X_{s-}, u)^2 \sigma(ds, du) \right) ds \right)^{1/2} \right]
\]

\[
+ C_{\lambda} \left( \text{E} \left[ \left( \int_0^{T\wedge \tau_n} \int_{U_0} (2 + X_{s-})^{2(\lambda-1)} 1_{\{g_0(X_{s-}, u) \leq 1\}|g_0(X_{s-}, u)|^2 \mu_0(du, ds) \right) \right)^{1/2} \right]
\]

\[
+ 2C_{\lambda} \text{E} \left[ \left( \int_0^{T\wedge \tau_n} \int_{U_0} 1_{\{0,1\}(\lambda)} + 1_{\{1,\infty\}(\lambda)}(2 + X_{s-})^{\lambda-1} \left( \int_{U_0} 1_{\{g_0(X_{s-}, u) > 1\}} |g_0(X_{s-}, u)|^\lambda \mu_0(du) \right) ds \right) \right]
\]

\[
\leq (\lambda \sqrt{K_1} + C_{\lambda} \sqrt{K_2}) \text{E} \left[ \left( \int_0^{T\wedge \tau_n} (2 + X_{s-})^{2\lambda} ds \right)^{1/2} \right]
\]

\[
+ 2C_{\lambda} K_{\lambda} \text{E} \left[ \int_0^{T\wedge \tau_n} \left( 1_{\{0,2\}(\lambda)}(2 + X_{s-})^{\lambda} + 1_{\{2,\infty\}(\lambda)}(2 + X_{s-})^{\lambda+1} \right) ds \right]
\]

\[
\leq (\lambda \sqrt{K_1} + C_{\lambda} \sqrt{K_2}) \sqrt{T(2 + n)^{\lambda}} + 2C_{\lambda} K_{\lambda} T \left( 1_{\{0,2\}(\lambda)}(2 + n)^{\lambda} + 1_{\{2,\infty\}(\lambda)}(2 + n)^{\lambda+1} \right).
\]
This shows that \((M_{t \wedge \tau_n})_{t \geq 0}\) is a martingale for each fixed \(n \in \mathbb{N}\). For the process \((A_{t \wedge \tau_n})_{t \geq 0}\) we use Lemma A.1 combined with conditions (3.a), (3.c), (3.d), and \((m)_\lambda\), to find that

\[
A_{t \wedge \tau_n} \leq \lambda \int_0^{t \wedge \tau_n} b(X_{s^-}) (2 + X_{s^-})^{\lambda-1} ds + \frac{\lambda(\lambda - 1)}{2} \int_0^{t \wedge \tau_n} (2 + X_{s^-})^{\lambda-2} \left( \int_E \sigma(X_{s^-}, u)^2 \varpi(du) \right) ds \\
+ C_\lambda \int_0^{t \wedge \tau_n} (2 + X_{s^-})^{\lambda-1} \left( \int_{U_1} 1_{\{g_1(X_{s^-}, u) \leq 1\}} |g_1(X_{s^-}, u)| \mu_1(du) \right) ds \\
+ C_\lambda \int_0^{t \wedge \tau_n} \left( 1_{(0,1]}(\lambda) + 1_{(1,\infty)}(\lambda)(2 + X_{s^-})^{\lambda-1} \right) \left( \int_{U_1} 1_{\{g_1(X_{s^-}, u) > 1\}} |g_1(X_{s^-}, u)|^2 \mu_1(du) \right) ds \\
+ \tilde{C}_\lambda \int_0^{t \wedge \tau_n} (2 + X_{s^-})^{\lambda-2} \left( \int_{U_0} 1_{\{g_0(X_{s^-}, u) \leq 1\}} |g_0(X_{s^-}, u)|^2 \mu_0(du) \right) ds \\
+ \tilde{C}_\lambda \int_0^{t \wedge \tau_n} \left( 1_{(0,1]}(\lambda) + 1_{(1,2]}(\lambda)(2 + X_{s^-})^{\lambda-1} + 1_{(2,\infty)}(\lambda)(2 + X_{s^-})^{\lambda-2} \right) \cdot \\
\cdot \left( \int_{U_0} 1_{\{g_0(X_{s^-}, u) > 1\}} |g_0(X_{s^-}, u)|^{\max\{1,\lambda\}} \mu_0(du) \right) ds \\
\leq \left( K_0 \lambda + \frac{K_1 \lambda(\lambda - 1)}{2} + K_0 C_\lambda + K_\lambda C_\lambda + K_2 \tilde{C}_\lambda + K_\lambda \tilde{C}_\lambda \right) \int_0^{t \wedge \tau_n} (2 + X_{s^-})^\lambda ds
\]

Hence taking expectations in (A.17) yields

\[
\mathbb{E}[V_\lambda(X_{t \wedge \tau_n})] = \mathbb{E}[V_\lambda(X_0)] + \mathbb{E}[A_{t \wedge \tau_n}] \\
\leq \mathbb{E}[V_\lambda(X_0)] + c(\lambda) \int_0^t \mathbb{E}[V_\lambda(X_{s \wedge \tau_n})] ds,
\]

which gives \(\mathbb{E}[V_\lambda(X_{t \wedge \tau_n})] \leq \mathbb{E}[V_\lambda(X_0)] e^{c(\lambda)t}\). By the right-continuity of \(X\) we have \(X_{\tau_n} \geq n\) and hence

\[
\mathbb{P}[\tau_n \leq t] = \mathbb{P}[V_\lambda(X_{t \wedge \tau_n}) \geq V_\lambda(n), \ t \geq \tau_n] \\
\leq \mathbb{P}[V_\lambda(X_{t \wedge \tau_n}) \geq V_\lambda(n)] \\
\leq \frac{1}{V_\lambda(n)} \mathbb{E}[V_\lambda(X_{t \wedge \tau_n})] \\
\leq \frac{1}{V_\lambda(n)} \mathbb{E}[V_\lambda(X_0)] e^{c(\lambda)t}.
\]

Hence \(\tau_n \nearrow \infty\) a.s. as \(n \to \infty\), which implies that \(X\) is a.s. finite. The Lemma of Fatou finally yields \(\mathbb{E}[V_\lambda(X_t)] \leq \mathbb{E}[V_\lambda(X_0)] e^{c(\lambda)t}\).
(b) Let \( \tau_n \) be as in part (a). Applying here the Itô formula to \( \log(2+X_{t,\wedge \tau_n}) \) yields
\[
\log(2+X_0) + A^\log_{t,\wedge \tau_n} + M^\log_{t,\wedge \tau_n},
\]
where \((M^\log_{t,\wedge \tau_n})_{t \geq 0}\) and \((A^\log_{t,\wedge \tau_n})_{t \geq 0}\) are given by

\[
M^\log_{t,\wedge \tau_n} = \int_0^{t,\wedge \tau_n} E(X_{s-},u) \frac{1}{2 + X_{s-}} W(ds,du)
\]
\[
+ \int_0^{t,\wedge \tau_n} \int_{U_0} (\log(2 + X_{s-} + g_0(X_{s-},u)) - \log(2 + X_{s-})) \tilde{N}_0(ds,du),
\]
\[
A^\log_{t,\wedge \tau_n} = \int_0^{t,\wedge \tau_n} b(X_{s-}) \frac{1}{2 + X_{s-}} ds - \frac{1}{2} \int_0^{t,\wedge \tau_n} \int_E \sigma(X_{s-},u)^2 \frac{1}{(2 + X_{s-})^2} \nu(du)ds
\]
\[
+ \int_0^{t,\wedge \tau_n} \int_{U_1} (\log(2 + X_{s-} + g_1(X_{s-},u)) - \log(2 + X_{s-})) N_1(du,ds)
\]
\[
+ \int_0^{t,\wedge \tau_n} \int_{U_0} \left( \log(2 + X_{s-} + g_0(X_{s-},u)) - \log(2 + X_{s-}) - \frac{g_0(X_{s-},u)}{2 + X_{s-}} \right) \mu_0(du)ds.
\]

Similarly as in part (a), using the Burkholder-Davis-Gundy inequality, Lemma A.2, conditions (3.c), (3.d), and \((m)_\log\) we find that

\[
E \left[ \sup_{t \in [0,T]} |M^\log_{t,\wedge \tau_n}| \right] \leq E \left[ \left( \int_0^{T,\wedge \tau_n} \frac{1}{(2 + X_{s-})^2} \left( \int_E \sigma(X_{s-},u)^2 \nu(du) \right) ds \right)^{1/2} \right]
\]
\[
+ \left( E \left[ \int_0^{T,\wedge \tau_n} \frac{1}{(1 + X_{s-})^2} \left( \int_{U_0} 1\{|g_0(X_{s-},u)| \leq 1\}|g_0(X_{s-},u)|^2 \mu_0(du) \right) ds \right) \right]^{1/2}
\]
\[
+ 2C_\log E \left[ \int_0^{T,\wedge \tau_n} \mu_0 \left( \{|g_0(X_{s-},\cdot)| > 1\} \right) ds \right]
\]
\[
+ 2C_\log E \left[ \int_0^{T,\wedge \tau_n} \frac{1}{2 + X_{s-}} \left( \int_{U_0} 1\{|g_0(X_{s-},u)| > 1\}|g_0(X_{s-},u)| \mu_0(du) \right) ds \right]
\]
\[
\leq (\sqrt{K_1 T} + 2 \sqrt{K_2 T}) + 4C_\log K_\log T,
\]

where we have used that \( \log(1 + |g_0(X_{s-},u)|) \leq |g_0(X_{s-},u)| \) and

\[
\mu_0 \left( \{|g_0(x,\cdot)| > 1\} \right) \leq \int_{U_0} 1\{|g_0(x,u)| > 1\}|g_0(x,u)| \mu_0(du) \leq K_\log(2 + x).
\]
This shows that \( (M_{t∧\tau_n}^{\log})_{t\geq 0} \) is a martingale. Secondly, using also condition (3.a), we observe that
\[
|A_{t∧\tau_n}^{\log}| \leq K_0 \int_0^{t∧\tau_n} \frac{2 + X_{s-}}{2 + X_s} \, ds + \frac{1}{2} \int_0^{t∧\tau_n} \frac{1}{(2 + X_{s-})^2} \left( \int_E \sigma(X_{s-}, u)^2 \varphi(du) \right) \, ds
\]
\[
+ C_{\log} \int_0^{t∧\tau_n} \frac{1}{1 + X_{s-}} \left( \int_{U_1} 1_{\{|g_1(X_{s-}, u)| \leq 1\}} |g_1(X_{s-}, u)| \mu_1(du) \right) \, ds
\]
\[
+ C_{\log} \int_0^{t∧\tau_n} \frac{\mu_1(\{|g_1(X_{s-}, u)| > 1\})}{2 + X_{s-}} \, ds
\]
\[
+ C_{\log} \int_0^{t∧\tau_n} \frac{1}{1 + X_{s-}} \left( \int_{U_0} 1_{\{|g_0(X_{s-}, u)| > 1\}} |g_0(X_{s-}, u)| \mu_0(du) \right) \, ds
\]
\[
+ C_{\log} \int_0^{t∧\tau_n} \frac{\mu_0(\{|g_0(X_{s-}, u)| > 1\})}{2 + X_{s-}} \, ds
\]
\[
+ C_{\log} \int_0^{t∧\tau_n} \frac{1}{2 + X_{s-}} \left( \int_{U_0} 1_{\{|g_0(X_{s-}, u)| > 1\}} |g_0(X_{s-}, u)| \mu_0(du) \right) \, ds
\]
\[
\leq ((1 + 2C_{\log})K_0 + K_1/2 + 3C_{\log}K_0 + C_{\log}K_2)\ell,
\]
where we have used \( \mu_1(\{|g_1(x, \cdot)| > 1\}) \leq K_0(2 + x) \). Thus, taking expectations of \( \log(2 + X_{t∧\tau_n}) = \log(2 + X_0) + M_{t∧\tau_n}^{\log} + A_{t∧\tau_n}^{\log} \) and using the above estimate proves the assertion. \( \square \)
